UNITED STATES OF AMERICA, et al.,  
Plaintiffs,  
-vs-  
STATE OF WASHINGTON, et al.,  
Defendants.

CIVIL NO. 9 2 1 3  
DIRECT TESTIMONY OF  
J. E. LASATER

\* \* \*

This is the direct testimony of J. E. Lasater submitted on behalf of Defendant, Department of Fisheries, in this action. This Defendant expressly reserves the right to submit further testimony by Mr. Lasater, either oral or written, to rebut the testimony presented by the Plaintiffs in this case.

1 Q. Please give your full name and address.

2 A. My name is Jasper Elton Lasater and I reside at Route 8, Box 344G,  
3 Olympia, Washington.

4 Q. Where are you employed and what is your title?

5 A. I am employed by the Washington Department of Fisheries and my  
6 title is Assistant Director of Fisheries.

7 Q. What is your educational background?

8 A. I have a bachelor of science degree in fisheries from the College  
9 of Fisheries at the University of Washington. I took two  
10 quarters of post graduate studies to get several fisheries courses  
11 unavailable to me while getting my bachelor's degree. I have  
12 completed seminar courses in natural resources management at the  
13 University of California and at Penn State.

14 Q. Will you relate your experience in the fisheries field?

15 A. While in high school in 1940, I worked a summer in a fish hatchery  
16 near Libby, Montana, as a hatchery helper. While in college, I  
17 worked the summer of 1950 for the Oregon Fish Commission as a  
18 biological aide at Astoria, Oregon. There, I aided in studies of  
19 the trawl fishery and gathered biological data on the species of  
20 fish captured. During the summer of 1951 I was the boat operator  
21 of a 50-foot vessel chartered from the College of Fisheries by the  
22 School of Oceanography. The summer was spent investigating the  
23 physical characteristics of the waters of northern Puget Sound.

24 Beginning in April, 1951, I was employed by the  
25 Department of Fisheries as an assistant to the chemist at the  
26 Bowman's Bay Laboratory. In this position I worked on studies of  
27 the effects of pollution on young salmon by analyzing samples of  
28 waste and water for such things as dissolved oxygen, concentra-  
29 tions of waste materials, salinity, alkalinity and standardization  
30 of waste samples for testing. I also assisted in the care and  
31 feeding of test fish and equipment in experimental work.

32 In February of 1952, I was promoted to Biologist I at  
33 the same laboratory with the added duties of being in charge of

1 studies of the effects of pollutants on salmon food organisms  
2 and aided in studies of the conversion of young salmon from fresh  
3 water to salt water.

4 In October of 1956, I was promoted to Biologist III and  
5 made project leader in charge of sports fishery management and  
6 research for Puget Sound and the Strait of Juan de Fuca. Chief  
7 duties involved estimating salmon catches by species and area,  
8 the gathering of data on marked salmon and all pertinent biologi-  
9 cal data on the salmon being harvested. My duties were expanded  
10 in October of 1960 simultaneously with an advancement to  
11 Biologist IV. I then conducted sport fishery management for the  
12 entire state. My duties involved the design and execution of  
13 scientific experiments. In February of 1962, I was made a  
14 Biologist V and was put in charge of all marine management and  
15 research with responsibility for personnel, operations and budget  
16 of the projects concerned. My duties included the evaluation and  
17 action phases of management and research programs and I repre-  
18 sented the Department of Fisheries in interactions with other  
19 governmental agencies at all levels. I advised the Director of  
20 Fisheries concerning policies in fisheries management.

21 In February of 1964, I was asked to be Assistant Director  
22 of Fisheries by Director George Starlund and have remained in  
23 that position and am now assistant to Director Thor C. Tollefson.

24 In this position I specialize in the operations of the  
25 Department of Fisheries rather than administration. My chief  
26 duties within the department are to supervise the operations of  
27 the Divisions of Patrol, Management and Research, Hatchery, Engi-  
28 neering, and Stream Improvement. I represent the Department and  
29 the State of Washington in meetings and negotiations with organi-  
30 zations, Indian tribes, states, and the United States including  
31 negotiations with foreign governments.

32 Q. Directing your attention to the issue of treaty Indian fishing  
33 rights, is it the Department of Fisheries' position that treaty

1 Indians must fish under the same regulations as other citizens?

2 A. No. In the Puyallup case, the U. S. Supreme Court said that  
3 regulations for treaty Indians must be reasonable and necessary  
4 for conservation and meet appropriate standards. I believe that  
5 the all-citizen fishery can be restricted more severely and for  
6 other reasons than these.

7 Q. Are treaty Indian fisheries set apart in any way from other fish-  
8 eries by the Department of Fisheries?

9 A. Yes. The Department of Fisheries in its policy and in its pro-  
10 gram and budget documents to the Governor and the Legislature  
11 identify three classes of clients: treaty Indians, sport fisher-  
12 men, and commercial fishermen. In addition to this, a position  
13 has been set up assigning a fisheries biologist fulltime to work  
14 with Indian fishery matters. Part of his job is to establish  
15 regulations and procedures that are suitable to Indian people and  
16 to become familiar with Indians and their fisheries to better  
17 bring to our attention matters which should be used in managing  
18 Indian fisheries. The staff also has been advised that in recom-  
19 mending regulations for Indian fisheries, they are to consider  
20 that these regulations must meet the test of being both reasonable  
21 and necessary for conservation.

22 Q. What does the work "conservation" mean to you?

23 A. Conservation is the wise conduct of human affairs to preserve  
24 resources and use them in a prudent manner.

25 Q. Do you distinguish essential elements necessary in the practice  
26 of conservation?

27 A. Yes, a data base is essential so that judgments and decisions can  
28 be founded upon facts. Computer techniques have a phrase  
29 "garbage in, garbage out" and this applies to the human brain as  
30 well as computers. Human values must be factored in. Conserva-  
31 tion of a resource is for human beings whether the resource is  
32 to be experienced through the senses or be consumed. In fishing,  
33 such values include the manner of fishing and the ultimate use of

1 the fish caught from both a social and an economic viewpoint.

2 The most basic use of fish is for food and is to be counted in  
3 terms of calories and essential food elements.

4 Q. Are there other essential elements to be considered if conserva-  
5 tion of salmon is the issue?

6 A. Yes. Salmon are a renewable resource. If their habitat is main-  
7 tained and they are harvested at the proper rate, there will be  
8 salmon for use and enjoyment for all of foreseeable time.  
9 Further, salmon have a terminal maturity. They all die after  
10 spawning and individuals cannot be saved for the future. Within  
11 two to five years, depending upon the species, the harvest must  
12 be taken and the spawning stock secured to ensure another genera-  
13 tion of salmon.

14 Q. Is the regulation of the fishery necessary for conservation?

15 A. Yes. Salmon are public property until they are reduced to posses-  
16 sion by some individual. A fisherman has the incentive to catch  
17 salmon but rarely the knowledge to know, of his own accord, which  
18 fish must be allowed to escape. Further, the individual cannot  
19 be assured that other fishermen will not catch the salmon that he  
20 allowed to escape. History is consistent in that unregulated  
21 fisheries lead to depletion of the resource and conservation is  
22 not secured. Further, unless deterred, some people will fish or  
23 care for their catches in a manner that wastes the fish. If a  
24 set net is not tended for several days, the first fish caught will  
25 be rotten and unfit for human consumption. Last fall fisheries  
26 patrol officers seized a set gill net at the Stevenson area on  
27 the Columbia River with approximately 2000 pounds of rotten  
28 salmon in it. As another example of wasteful practice, I have  
29 heard it said that if the Indians wished to use explosives, such  
30 as dynamite, to kill fish, they would be within their treaty  
31 right to do so. Explosives can be used for fishing. Many of the  
32 fish that are killed by an explosion, however, sink and are not  
33 recovered. Immature fish, food organisms, and other plants and

1 animals essential to the ecological balance of the aquatic envi-  
2 ronment are injured or destroyed.

3 Q. Are regulations necessary for conservation always restrictive?

4 A. No, I can remember that during the large 1958 sockeye run fisher-  
5 men in northern Puget Sound were given over 20 straight days of  
6 fishing with no closure. We have encouraged the Lummi Indians to  
7 fish for 7 days a week on the reservation when fall chinook of  
8 hatchery origin are dominant in the Nooksack River. We have  
9 asked the Skokomish Indians to fish 7 days a week in the Skokomish  
10 River for hatchery coho. On large runs it is necessary to fish  
11 hard for conservation purposes and regulations reflect this.

12 Q. Is it necessary for conservation that fishing in different areas  
13 in rivers be managed differently?

14 A. Yes. Salmon migrating from the ocean commonly delay at the river  
15 mouth and often at the lower reaches of the river. These are  
16 designated as milling areas. Proper regulation should allow some  
17 number of salmon to be caught and some number to escape. In a  
18 milling area salmon are subjected to nets repeatedly and escape-  
19 ment cannot be ensured. A weekly closure for escapement may go  
20 by and at the resumption of fishing the same salmon are still  
21 there. Net fishing is allowed in milling areas only under  
22 special circumstances and such fisheries usually involve hatchery  
23 stocks. As salmon leave the milling area and move upstream, they  
24 usually move steadily through an area that we call waters of  
25 passage. It is here that a portion of the run may be removed and  
26 the remainder of the fish will move upstream beyond the fishing  
27 area. Spawning escapement can be ensured if proper gear restric-  
28 tions and fishing times are applied. Next upstream there will be  
29 holding water where the salmon congregate awaiting spawning time.  
30 Depending on the species and race of salmon, the waiting period  
31 may extend from a few days to several months. Salmon in holding  
32 areas present the same problems as fishing in milling areas and  
33 are even more confined. In addition, since they will no longer

1 feed and must exist and spawn using body reserves, harassment  
2 will use up irreplaceable stores of energy and can be expected to  
3 cause death prior to spawning. Such a loss of salmon is wasteful  
4 and diminishes the numbers of fish in the next generation.  
5 Spawning grounds will be found near the holding areas and gener-  
6 ally upstream. Spawning salmon are a stationary group of salmon  
7 with even less of an energy store than in the holding areas.  
8 Further, harassment of salmon on the spawning grounds directly  
9 interferes with the act of spawning. Spawning areas should be  
10 closed to fishing.

11 Q. Is a particular area in a river always a spawning area or a hold-  
12 ing area?

13 A. No. There are five species of salmon and a number of races with  
14 different times of migration and spawning areas. A given portion  
15 of a river may be spawning area for one species and water passage  
16 for another. If they are also separated in time, the area might  
17 be fished at one time and closed to fishing at another time.  
18 Each river must be fished according to its physical characteris-  
19 tics and the species of salmon which inhabit it. Exhibit F-1 is  
20 illustrative of the different areas on a river to which I have  
21 referred.

22 Q. We have used the term "manage" in referring to the need to achieve  
23 necessary conservation goals. Could you define what management  
24 is as it pertains to the salmon resource?

25 A. Management is a term that includes all of the organized activities  
26 of man aimed at conservation of a resource. Management can be  
27 separated in three main categories: (1) activities maintaining  
28 or creating an environment so that salmon may be produced in  
29 abundance; (2) regulations which ensure that sufficient salmon  
30 escape the fishery to ensure production of the next generation of  
31 salmon and, (3) regulations which ensure, to the extent possible,  
32 that all salmon not needed for spawning are harvested and used.

33 Q. Are the fisheries for salmon divisible into categories which

1 require different goals in management?

2 A. Yes, there are separate goals for the all-citizen commercial  
3 fishery, the sport fishery, and Indian fisheries.

4 Q. What are your department's goals for the all-citizen commercial  
5 fishery?

6 A. One goal is that the harvestable portion of a salmon run is regu-  
7 lated in such a manner that a fisherman has the opportunity to  
8 catch fish in quantities that will afford him a profit for his  
9 labor and his investment. A second goal is that salmon will be  
10 processed and marketed so that the public at large will be able  
11 to buy salmon for consumption. A third goal is that the economy  
12 and well-being of all of our citizens will be enhanced by use of  
13 the resource.

14 Q. What are your department's goals for the sport fishery?

15 A. One goal is a maximization of the recreational opportunity con-  
16 sistent with wise management. A second goal is that salmon are  
17 made available for the personal use of those who wish to fish.  
18 A third goal is that the fishery will enhance the economy and  
19 well being of all citizens by use of the natural resources of the  
20 state.

21 Q. What are your department's goals for the Indian fisheries?

22 A. The goals for the commercial Indian fishery are similar or  
23 identical with the goals for the all-citizen commercial fishery.  
24 In addition, it is our goal to make salmon available for the  
25 personal use of Indians who wish to fish. A goal unique to  
26 Indian fisheries is to make salmon available for ceremonial fish-  
27 eries which have to do with their culture and religion.

28 Q. Are the fisheries that you have indicated managed differently?

29 A. Yes.

30 Q. In what way are they managed differently?

31 A. Commercial fisheries, both Indian and all-citizen, are limited in  
32 time and area but when allowed to fish there are no restrictions  
33 on the amount of salmon that can be taken by any individual.

1 Further, by their nature, different types of commercial gear are  
2 regulated differently. A reef net fishes at a set location and  
3 is dependent upon visual sightings of salmon and is fished only  
4 during daylight hours. Gill net boats are mobile and the nets  
5 work best in dim light so that fishery is confined largely to  
6 night hours. Purse seines are mobile and are a daytime gear.  
7 Trollers fish during the daytime with lures and are confined to  
8 the ocean. They fish over a relatively long season without  
9 intervening closed periods to meet the market demand for fresh  
10 salmon over a longer period of time. Most Indian commercial  
11 fisheries are in the rivers where set gill nets and drift gill  
12 nets are used. These fisheries occur on salmon which have left  
13 the more open marine areas and entered a funnel, so to speak.  
14 Since the fish are so confined and concentrated between two banks,  
15 the fishery must be carefully regulated to prevent over fishing.  
16 The sport fishery fishes for a longer period during the year than  
17 commercial fisheries in order to ensure a maximum recreational  
18 opportunity. The daily allowable catch is limited so that a long  
19 season can be allowed and meet conservation needs. Further, a  
20 bag limit is compatible with both recreational and personal-use  
21 goals. This principle is also exercised for treaty Indian fish-  
22 ing on the Columbia River where personal-use fisheries are  
23 allowed with dip nets and spears at places and at times that  
24 commercial fishing with gill nets is not allowed. Indian fisher-  
25 men and their tribal leaders have expressed to me that they place  
26 a higher value on personal-use fisheries than upon commercial  
27 fishing. At a meeting in Department of Fisheries' offices,  
28 Yakima tribal leaders told me that their priorities ranked as  
29 follows: 1. salmon for ceremonial purposes; 2. salmon for  
30 personal use; 3. salmon for commercial sale. While at present  
31 no personal use seasons have been established in the case area,  
32 the department is willing to establish such fisheries for treaty  
33 Indians.

1 Q. Does the migratory nature of salmon affect regulations designed  
2 to conserve the resource?

3 A. Yes. As salmon migrate from the ocean to Puget Sound then to a  
4 river, they may be fished in all of these places. If all of the  
5 available harvest is taken in the ocean, then for conservation  
6 purposes Puget Sound and the rivers must be closed to fishing to  
7 obtain the spawning escapement. If all of the harvest is taken  
8 in marine waters, the rivers must be closed. The regulation  
9 pattern can create the need for closure for conservation purposes  
10 at a later time and in a different area of the migratory route.

11 Q. Is a regulatory standard that regulation must be "reasonable and  
12 necessary for conservation" and "meet appropriate standards"  
13 sufficiently precise to manage an Indian river fishery in Puget  
14 Sound and on the Olympic Peninsula coastal rivers?

15 A. No. The demand for salmon is such that all salmon taken can be  
16 disposed of, so lack of demand will not stop the fishery. If the  
17 conservation test were literally applied, other fisheries in the  
18 ocean and Puget Sound would have to be curtailed as the river  
19 fishery grew so that spawning escapement could be ensured. At  
20 some point all other fisheries would have to be completely closed  
21 and only then would it be literally necessary to halt the growth  
22 of the river fishery to conserve the resource. The converse  
23 would also be true. Too liberal regulation of salmon fishing in  
24 marine waters could bring about the closure of an Indian river  
25 fishery as being necessary for conservation. But since Indians  
26 and other citizens should have opportunities to catch fish, then  
27 the question of when it is reasonably necessary for conservation  
28 to close a fishery is more complex. Fair treatment for all fish-  
29 ing groups requires that standards be set for management so that  
30 all groups share the catch in a manner that will be fair to Indian  
31 treaty fishermen and to the all-citizen fishery.

32 Q. Is this fair share principle an essential element of managing  
33 an Indian river fishery to meet conservation needs?

1 A. Yes. The all-citizen fishery must be regulated so that treaty  
2 Indians have an opportunity to catch a fair share of the salmon  
3 harvest. Once a fair share is determined, the Department of  
4 Fisheries should be required to regulate the fisheries in such  
5 a manner that such opportunity is presented. The problem for us  
6 is that the courts tell us our regulations for an Indian fishery  
7 must be "reasonable and necessary for conservation" and "meet  
8 appropriate standards" but then never tell us what those terms  
9 mean. As I just pointed out, there is always a conservation  
10 necessity to regulate any fishery. Judge Belloni in Oregon  
11 interpreted these terms to mean that the Indians must have an  
12 opportunity to catch a fair share of the harvest. We accept that  
13 principle, but the term "fair share" is vague like the term  
14 "conservation" when you attempt to apply it in a management plan.  
15 What we need is direction from the court as to what would con-  
16 stitute a "fair share". We are hopeful this lawsuit will resolve  
17 this problem so that we can stop being harassed by lawsuits each  
18 time we pass a regulation and let us get on with our job which is  
19 to manage the fishery in the best interest of all of our citizens,  
20 Indians and non-Indians.

21 Q. If this court simply adopted the ruling of Judge Belloni in the  
22 Sohappy case to which you just referred, would that solve the  
23 problem of giving the department an appropriate standard by which  
24 to meet the requirement of a fair share?

25 A. No. We have adopted the principle of the decision by Judge  
26 Belloni to attempt to ensure Indians a fair share of the catch.  
27 He did not, however, define a "fair share". The result has been  
28 that many Indians are not satisfied with their share or with the  
29 fishery and have gone to court several times on the matter.  
30 Furthermore, the Columbia River fishery is quite different in  
31 character than the fishery in Puget Sound and has to be managed  
32 differently so that the decision or principles adopted there  
33 cannot be literally applied to a Puget Sound fishery.

1 Q. You mentioned that the Columbia River "fair share" plan is not  
2 appropriate for managing the Puget Sound and coastal rivers  
3 involved in this lawsuit. Why is that?

4 A. The fishery on the Columbia River involves an all-citizen fishery  
5 in the lower portion and an Indian fishery in the upstream area.  
6 The stocks are relatively unmixed or at least all Columbia River  
7 stocks are tending to be on a single migration path and can be  
8 followed directly from one area to the next. In Puget Sound we  
9 have diverse runs going to many rivers, mixed stocks, mixed  
10 species, and many different and more complex management problems.  
11 For instance, in the Columbia River on runs bound for above  
12 Bonneville Dam restriction of the all-citizen fishery will  
13 directly augment the Indian catch and the effect on escapement  
14 will be known with considerable precision. In Puget Sound a  
15 blanket restriction in northern Puget Sound, where there are mixed  
16 stocks of a number of species from many rivers, will have other  
17 effects, often adverse, than just increasing treaty Indian  
18 catches. For example, a blanket restriction could cause us  
19 serious difficulties with over escapement in rivers and streams  
20 where there are not Indian fisheries. In order to properly  
21 manage the fishery we need a definition of a fair share that fits  
22 Puget Sound and the coastal rivers and the Belloni decision does  
23 not do this.

24 Q. Does the Department of Fisheries have a management model to  
25 recommend to the court for the Puget Sound and coastal river area  
26 involved in this case?

27 A. Yes, we do. In general, this model would set aside for the  
28 Indians a percentage of the harvest from the fish produced by the  
29 rivers involved in their treaty fisheries. The percentage would  
30 be applied to the catch that is taken under state jurisdiction in  
31 areas that can be regulated by the State Department of Fisheries.  
32 It would then be the responsibility of the state to manage the  
33 fishery to ensure that this fair share reached the Indian fisher-

1 men.

2 Q. If the State of Washington is to be responsible for ensuring  
3 that the treaty Indians have an opportunity to catch a fair  
4 share of the salmon, should all salmon landed in the State of  
5 Washington be counted in determining the size of the harvest from  
6 which the Indians' share is to be measured?

7 A. No. The total Washington landings cannot be used to arrive at  
8 a fair share for two reasons: First, many salmon are caught and  
9 landed in the state that are bound for areas separate from treaty  
10 fishing areas. Many salmon caught in the ocean off our coast and  
11 landed in our state originate in California, Oregon or Canada.  
12 Catches of salmon in the Strait of Juan de Fuca through the San  
13 Juan Islands and northward to Canada are often fish bound for  
14 Canadian streams and particularly the Fraser River. Further,  
15 large areas, such as Willapa Bay, are not the usual and accustomed  
16 fishing places of treaty tribes. Only those salmon which are  
17 native to treaty fishing areas should be counted in determining  
18 a fair share because it was only those fish that the Indians in  
19 treaty times had an opportunity to fish for. Secondly,  
20 Washington cannot be held accountable for salmon harvested out-  
21 side of its jurisdiction. Large quantities of salmon which are  
22 spawned in rivers and streams within the case area are harvested  
23 outside of state waters in international waters. This is some-  
24 times a major portion of the catch of some species. Salmon so  
25 caught are taken by fishermen from other states as well as by  
26 Canadians. The state can likely regulate its own citizens in  
27 international waters, but cannot regulate the ocean fisheries to  
28 ensure that any particular share will migrate back to state  
29 waters. In setting up a fisheries management zone between three  
30 and twelve miles off shore, Congress specifically excluded state  
31 jurisdiction in those waters. The state cannot license fishermen  
32 or collect a landing tax for fish from outside of three miles of  
33 its shores. If further restrictions are necessary in inter-

1 national waters to ensure a fair share to treaty Indians, such  
2 regulations are within the jurisdiction of the United States  
3 Government. If the Canadian take is to be curtailed, the United  
4 States Government alone has the power to negotiate or reach  
5 agreement with Canada. The State of Washington cannot be respon-  
6 sible for matters outside of its jurisdiction.

7 Q. Is there a problem in ensuring that salmon native to areas fished  
8 by treaty Indians escape the ocean fishery?

9 A. Yes. The offshore fishery for chinook and coho salmon is taking  
10 a major portion of the harvest of those species and has led to  
11 severe restriction of the fishery in Puget Sound. Figures used  
12 by the United States in negotiating with Canada this year show  
13 that Canadian fishermen are taking approximately 83 percent of  
14 Puget Sound chinook salmon and approximately 65 percent of the  
15 coho.

16 Q. Should any salmon taken under the jurisdiction of the Inter-  
17 national Pacific Salmon Fisheries Commission count toward a fair  
18 share?

19 A. Yes. The Commission's regulatory activities are in the Strait  
20 of Juan de Fuca and northern Puget Sound, as explained in the  
21 joint biological statement on pages 101 to 103. The State of  
22 Washington, through its Director of Fisheries, shares in the  
23 management decisions of the Commission, and United States fisher-  
24 men fishing under regulations recommended by the Commission are  
25 licensed and otherwise regulated by the state. Salmon bound for  
26 Indian treaty fisheries should be counted, but salmon bound for  
27 Canada should not be counted.

28 Q. In the management model you have proposed, why is the fair share  
29 determined in a percent of the available harvest spawned in the  
30 rivers within the case area on which there are Indian fisheries?

31 A. Essentially there are three reasons: (1) a percentage share  
32 affords a definite standard necessary for management planning;  
33 (2) a percentage share is conservationally sound; and (3) it is

1 the fairest method.

2 It is essential in planning the management of a complex  
3 area like this, where there are several fisheries, that we have  
4 fixed standards to work toward. If a fisheries manager asks me  
5 what to do and I tell him only that his management plan must be  
6 fair, he won't know how many fish should go where, and his plan  
7 will be indefinite and subject to constant challenge.

8 You have to understand how a manager works in order to  
9 appreciate the need for a definite standard to be applied to the  
10 fair share principle. The manager must take all the data avail-  
11 able to him on the fisheries, including the species of salmon  
12 approaching, their probable migration route, their predicted run  
13 strength, and the expected fishing effort to carefully make  
14 estimates and plans as to how the fish will behave and how the  
15 fishermen will behave and where the catch will be taken. This  
16 must be done with considerable precision so that we have an idea  
17 of how the fishery will go in a particular year. Then we have a  
18 framework which can be modified as the fish show up, so that we  
19 can react to the actuality of the fish run that presents itself.  
20 Without a precise goal, it is impossible to plan, and advance  
21 planning is essential if the harvest of the fish is to be properly  
22 managed and the resource conserved. Time is of the essence,  
23 because the fish don't wait. They move very, very quickly.  
24 Salmon can move from the Strait, completely through the Sound and  
25 be in other fisheries in three days. Thus, I would say that any  
26 definition of a fair share must lend itself to a management plan  
27 that affords an opportunity for precise advance planning of the  
28 harvest. A fair share based on a percentage of the harvest meets  
29 this requirement because it gives us a definite goal to be work-  
30 ing toward in planning the harvest in any given year.

31 As for the conservation of the resource, achievement of  
32 the necessary spawning escapement has to be the final goal. Thus,  
33 the management system has to allow the harvest to reflect the

1 actual run size of fish and vary with it and not separate from it.  
2 The percentage share does just that, since in abundant years the  
3 share is increased and in lean years it is reduced automatically.

4 Finally, the plan will be fair. Once the decision is  
5 made as to what percentage constitutes a fair share, then the  
6 management agency can plan and work toward that goal and achieve  
7 it and, I think, achieve it with regularity. If a run is poor, no  
8 one fishery is penalized more than another - all have to share in  
9 a reduced harvest. Conversely, if a run is large, all fisheries  
10 can share in the bounty thereof and no one then is short of fish  
11 due to some other standard that is not related to the size of the  
12 fish run.

13 Q. Why not just set a fixed quota for the Indian catch?

14 A. The fixed quota system would provide for a fixed standard. The  
15 fixed quota, however, does not meet sound conservation practices.  
16 On years when the run is low, the quota catch may very well  
17 exceed the number of fish available for harvest and the quota of  
18 fish will be taken directly from necessary spawning escapement.  
19 For instance, this year we expect a very small run of chinook  
20 salmon to return to Puget Sound from international waters. We  
21 have closed the commercial fishery and reduced the sport fishery.  
22 An Indian commercial net fishery with a fixed quota on this run  
23 could be expected to reduce the spawning escapement below neces-  
24 sary or desirable levels, and that would be unsound conservation.  
25 Furthermore, a fixed quota will be unfair to fishermen, both  
26 Indian and non-Indian, and may well be unfair to the state. On a  
27 year when the run is low and the Indian quota will take the  
28 entire harvest, the all-citizen fishery then must be entirely  
29 shut down to meet spawning escapement goals. On a year when the  
30 run is very good, the Indian will be fixed to a quota which will  
31 be low on that year and the all-citizen fishery will have a  
32 bountiful harvest and the Indian will only catch his fixed quota.  
33 Some years the return, and it may be true this year with chinook

1 salmon, would be so low that the state would be in the position  
2 of having legally to see that the Indians got a particular quota  
3 of salmon when that number might not even enter its jurisdiction  
4 at all. It would be unfair to the state to penalize us in such  
5 a situation. All fishermen want the opportunity to make a large  
6 catch and to fish with the least possible restrictions within any  
7 regulation plan adopted. A fixed quota is rigid and would  
8 depress a fisherman's ability to use all of his skills to the  
9 utmost. In addition, a fixed quota is foreign to the Indian  
10 manner of fishing. Even in treaty times and before, run sizes  
11 fluctuated due to combinations of natural circumstances and the  
12 Indian catches reflected this run strength.

13 A comparison can be shown between the workings of a  
14 percentage share and a fixed quota management system. Suppose  
15 that a particular run of salmon averages 5000 salmon. Escapement  
16 needs are 1000 salmon, thus 4000 salmon should be harvested.  
17 Assume that treaty Indians are to catch 20 percent of the harvest.  
18 If a quota is set it will be 800 salmon annually. If the run is  
19 average, or 5000 salmon, both the percent share and the quota  
20 is 800 salmon and the escapement goal of 1000 salmon can be  
21 reached. With a poor run of 1500 salmon, only 500 salmon are  
22 available for harvest and a 20 percent share is 100 fish. If a  
23 quota of 800 salmon is taken, the escapement goal will not be  
24 met as only 700 salmon will remain. Further, all other fisheries  
25 must be entirely closed and not share in the harvest. If the  
26 run is 10,000 salmon, 9,000 will be available for harvest. A  
27 20 percent share is 1800 salmon and the escapement goal will be  
28 met. If these three years are summed up, under a percent share  
29 the spawning escapement would have been met each year and conser-  
30 vation served. In addition, the total Indian take would be 2700  
31 salmon. With a quota, escapement needs would have been short by  
32 30 percent on one year and the Indian take would be 2400 salmon  
33 so that under the quota, both escapement and the Indian catch

1 would suffer. I have illustrated these three examples on  
2 Exhibit F-2.

3 Q. In the examples you have used, there was widely fluctuating run  
4 size. Would fluctuations typical of those presented in the  
5 example be found in the river systems and watersheds involved in  
6 the case area?

7 A. Yes, they will be found. Survivals vary due to combinations of  
8 weather, river flows and such, and at times the result of spawn-  
9 ing is that only one salmon or less returns for every salmon that  
10 spawns. We have had examples of where one salmon produced as  
11 many as 20 returning fish on the ensuing run, so that while I  
12 have shown examples that varied less than one in ten, we do have  
13 examples where runs have varied as much as 1 in 20.

14 Q. Do you have access to any statistics which would verify this  
15 fluctuation in run size which your example refers to?

16 A. Yes, I have. I can refer to the 1970 Fisheries Statistical  
17 Report of the Washington Department of Fisheries and find such  
18 examples. In the table on page 38, labeled Catch of Salmon on  
19 Puget Sound Excluding Off-Shore Catches and Number of Fish, there  
20 are a number of examples.

21 Q. Is the 1970 Fisheries Statistical Report a business record of the  
22 Department of Fisheries that is kept in the normal course of its  
23 business by the department?

24 A. Yes, it is.

25 Q. We will designate the 1970 Fisheries Statistical Report as  
26 Exhibit F-3 and request that it be admitted into evidence. Now,  
27 referring to the table that you mentioned on page 38 of Exhibit  
28 F-3, could you give us an example of this fluctuation?

29 A. Yes. This table is of the catches of salmon in Puget Sound from  
30 the year 1913 forward and in recent years. There are any number  
31 of examples here, but I can refer to the catch of silver salmon  
32 in 1960, which was less than 104,000 salmon, and to the catch in  
33 1970 which was very nearly 850,000 salmon. Between these years,

1 catches fluctuated less extremely but were at times double other  
2 years.

3 Q. Why not just cut back on the all-citizen fishery in marine waters  
4 so that the treaty Indians can catch more salmon?

5 A. First, there would be no fixed standard so that the fisheries  
6 manager could plan a management outline for the coming season.  
7 He has no way of knowing how much to cut back, how many salmon  
8 the Indians will catch so that he can plan through to the spawn-  
9 ing escapement. In these circumstances the manager might esti-  
10 mate how much he should restrict the all-citizen fishery and he  
11 might estimate how many fish the Indians might take and how hard  
12 they might fish and he might be wrong in either or both of these  
13 areas and find that he doesn't have enough fish left over to  
14 meet spawning escapement needs and conservation suffers. Further,  
15 the plan is not conservationally sound because our experience in  
16 trying to manage for the reservation fisheries is that there is  
17 a tendency of Indians to fish without regard to run size. In  
18 some cases overfishing has occurred because the Indian fishery  
19 does not properly reflect the size of the run and the capability  
20 of that run to produce a harvest over and above the spawning  
21 escapement. Nor will fairness be achieved by such a method  
22 because there is no way of knowing what share is fair to either  
23 fishery. You make estimates of what each will catch and chances  
24 are that neither fishery will believe that they have received a  
25 fair share.

26 Q. In the past, you have regulated the fishery to make an allowance  
27 for reservation catches without any authority to regulate on the  
28 reservation. Why can you not now just cut back the all-citizen  
29 fishery to make an allowance for an off-reservation fishery?

30 A. First, I would note that such management has not been without  
31 its conservation problems as I mentioned previously. But there  
32 is also an important difference between managing for an esti-  
33 mated reservation catch and an estimated off-reservation catch.

1 Reservations are fixed in location and in size. The physical  
2 limits of a reservation on a river limit the number of favorable  
3 places to fish and, therefore, a reservation fishery is by its  
4 nature self-limiting. But we are talking about an off-reservation  
5 fishery in which the plaintiffs claim usual and accustomed fish-  
6 ing grounds in all the streams, rivers and marine areas of the  
7 case area. There is nothing to limit such an Indian commercial  
8 fishery. The market for salmon is such that it can absorb all  
9 the available fish. They are valuable and the incentive to catch  
10 the fish is there, there is money to be made. In our experience,  
11 such fisheries will expand until something stops them. That  
12 something may be regulations or it may be that the catch becomes  
13 so great that spawning escapements suffer and the runs subse-  
14 quently decline and conservation is not served.

15 Q. Do you know of any examples in the Indian fisheries where such  
16 an expansion occurred?

17 A. Yes, I do. That, for instance, was what the Puyallup case was  
18 all about in the original. A fishery began and expanded till  
19 the river fishery was at a maximum level; the fishery expanded  
20 with larger and larger and more complex nets to Commencement Bay  
21 at Tacoma so that the catch exceeded anything that the river  
22 could produce. Escapements to the hatchery and wild escapements  
23 suffered, and the total production of the river subsequently  
24 declined, as indicated in Exhibit F-4.

25 Q. We will submit Exhibit F-4 for illustrative purposes. Could you  
26 manage an Indian river fishery if the requirement were that your  
27 regulations meet a test of being the least restrictive regula-  
28 tions that would be reasonable and necessary for conservation?

29 A. No, I don't believe that we could. I don't think that we can  
30 ever meet that standard. I don't know of any management plan  
31 that I have ever seen or helped devise or have worked with that  
32 I, myself, could not challenge as not being more restrictive in  
33 some measure than some other plan. I am quite sure that such a

1 plan cannot be devised. It will always be open to such criticism  
2 because the term "least restrictive" becomes a matter of opinion  
3 and judgment and is not tied to the objective factual picture in  
4 any definite way. At present, the Department of Fisheries must  
5 show that its regulations are reasonable and necessary for con-  
6 servation. We could better meet this if fixed standards are set.  
7 We cannot and will not be able to prove the negative, however,  
8 i.e., that no other system can be devised which is less restric-  
9 tive.

10 Q. If Indian tribes could successfully show that their regulations  
11 were less restrictive than the regulations proposed by the state,  
12 what would be the effect on the management process if the court  
13 were to impose on the department the tribal regulations?

14 A. First, I would expect the Indian tribes to always be able to  
15 devise a less restrictive regulation than put forward by the  
16 department because up until the time the all-citizen fishery is  
17 reduced to zero, they will always be able to show that the  
18 department can meet the test of conservation by shutting down  
19 other fisheries. In this case, also, management will be so  
20 fragmented that it will be impossible to plan a rational fishery  
21 which meets the needs of conservation and, in fact, ensures a  
22 fair share to Indians. Furthermore, management will be taken out  
23 of our hands and placed in the hands of the court. My under-  
24 standing of the Puyallup decision is that regulation of Indian  
25 off-reservation fisheries is the responsibility of and is under  
26 the authority of the state. It is critical that Indian input  
27 into the regulation-making process comes prior to the adoption of  
28 the regulations. Our state Administrative Procedures Act provides  
29 full opportunity for Indians to participate in the regulatory  
30 process. In addition, the department will and has made special  
31 efforts to include Indians in this regulation-making process. If  
32 the "least restrictive" standard applies, I would expect Indians  
33 in each case to prepare less restrictive regulations, and if they

1 were successful in challenging the state regulations, the entire  
2 regulation pattern for that season would be in jeopardy. Multiply  
3 that situation times the thirteen tribes who are plaintiffs in  
4 this law suit and you can imagine the chaos that would result in  
5 our management program.

6 Maybe if I give you a capsule summary of the steps taken  
7 to adopt regulations, you will appreciate why the Indian contri-  
8 bution should come in the planning stage instead of after the  
9 regulations' adoption in a court test over whether their regula-  
10 tions are less restrictive than ours. We have indicated the  
11 planning process in Exhibit F-5 which is illustrative. As soon  
12 as one salmon season is over and the data processed, planning  
13 begins for regulation of the next season's fishery. Months are  
14 required to make and refine predictions and test ideas for  
15 managing the runs brought up by department experts. The sug-  
16 gested plan is studied and alternatives weighed up to the  
17 director's level. The Administrative Practices Act procedures  
18 are brought into play, requiring at least 20 days between noti-  
19 fication and a hearing. Hearings are held and the input received  
20 there evaluated and factored into the plan. The regulations must  
21 be adopted prior to first salmon runs in late spring and in time  
22 for notification of fishermen so that they, too, can plan their  
23 fishing season. If, after regulations are adopted, they are  
24 successfully challenged, there is no way to replan the fishing  
25 season before the salmon arrive. A far better standard is a  
26 method which would test the reasonableness and necessity for con-  
27 servation against some definitive fair share principle.

28 Q. If a tribe fishes in marine waters where stocks of salmon from a  
29 number of streams occur, how might the treaty right be met?

30 A. In this case, Indians would be scheduled for more fishing time  
31 than is scheduled for the all-citizen fishery. For example, it  
32 would not be proper or possible to ensure the Makah Indians a  
33 particular share of all of the salmon in their usual and

1 accustomed fishing area. Salmon originating from California to  
2 British Columbia are found off Neah Bay. Instead, the Department  
3 of Fisheries has set a year-round troll salmon season for Makah  
4 Indians near the reservation and schedules more net fishing days  
5 in the Strait of Juan de Fuca than are allowed other fishermen.  
6 Similarly, the Squaxin Indians and the Tulalip Tribe may fish in  
7 certain areas within salmon preserves where no other people can  
8 fish with nets.

9 Q. Can the Department of Fisheries manage the Indian treaty fishery  
10 and the all-citizen fishery to prevent waste and over escapement?

11 A. Yes, provided that the plan for ensuring the treaty Indians a  
12 fair share is flexible so that the Department of Fisheries can  
13 set regulations which will respond to vagaries of run size and  
14 migration by species and race as well as weather and the changing  
15 of fishing patterns by Washington fishermen. A fair share  
16 expressed in percent of production leaves the management of the  
17 fishery in the hands of people trained and experienced in fisher-  
18 ies management.

19 Q. Have you arrived at any principles which would apply to the  
20 proper use of a flexible management plan based upon fixed  
21 standards such as the percentage share system you have proposed?

22 A. Yes. First, such flexibility is not to be used to detract from  
23 the treaty Indian catch. The need for such flexibility may  
24 often be used for conservation as well as fair distribution of  
25 the catch. For instance, in 1973 the chinook run is expected to  
26 be very small and should be protected. However, closely follow-  
27 ing and partly overlapping the chinook run we expect a large coho  
28 run. The large coho run should be harvested, but in so doing  
29 some late-running chinook will be taken. The department then  
30 could say that the coho must be taken for conservation purposes,  
31 but no chinook remain for the Indian catch also for conservation  
32 purposes. The percentage fair share would ensure the Indians  
33 their percentage of the harvest regardless, either directly or

1 to be made up in another species (for instance the coho) or as a  
2 debit to be made up the following year. Secondly, the manner  
3 and time of the all-citizen fishery is not a concern under the  
4 treaty right unless it detracts from the treaty right or physi-  
5 cally interferes with fishing by treaty Indians. The claims or  
6 jealousies of other fishermen which are very common in fisheries  
7 management are without justification for the treaty Indians if  
8 they are in fact catching their fair share. The catch is the  
9 proof that other fisheries are being curtailed so as to meet the  
10 treaty right. Further, the state can then exercise its regula-  
11 tory authority freely in managing the manner and places of fish-  
12 ing of its non-treaty citizens.

13 Q. Must all of the treaty Indians catch the fair share percentage in  
14 order that the treaty right can be met?

15 A. No. If the state can demonstrate that sufficient salmon were  
16 allowed to escape to the Indian fishery, but due to conditions  
17 beyond its control or reckoning the Indians did not catch a fair  
18 share, the state has met its obligations. Situations could occur  
19 where the Indians would make an insufficient effort to catch the  
20 salmon. A severe price drop could reduce fishing effort; a  
21 disaster such as a fire could destroy the fishing gear; or a sale  
22 of reservation timber and subsequent individual benefits might  
23 make the hard labor of fishing temporarily unattractive. Further,  
24 a natural disaster such as storms, floods, drought or changes in  
25 the behavior of the salmon might curtail the catch. Such  
26 occurrences are well known in the history of fishing and will  
27 always affect fishermen. When such things truly occur and can be  
28 documented, the state should not be penalized.

29 Q. Do you have any guidelines which have to do with the manner of  
30 fishing or the gear used by treaty Indians in the taking of  
31 salmon?

32 A. Yes. The state should seriously consider any method of taking  
33 salmon which is traditional to the Indian people or modern

1 methods and gear where it is applicable. The wishes of the tribe  
2 should be strongly considered in this regard. The state should  
3 be able to reject frivolous or negative practices. Under a  
4 "least restrictive" standard the state might be forced to prove  
5 that a particular poison should not be used or some mechanical  
6 fish-catching device quite foreign to the traditions of Indian  
7 and non-Indian alike.

8 Q. Could the wishes of the Indians affect the manner of fishing?

9 A. Yes, it could and the regulations of the Department of Fisheries  
10 reflect this. I believe the treaty right is a tribal right and  
11 that the tribe may wish controls beyond those deemed necessary  
12 by the Department of Fisheries. For instance, in the off-  
13 reservation area on the Nisqually River the tribe asked that our  
14 regulations include a minimum gill net mesh restriction of 6-1/2  
15 inches and a weekend closure. Both were adopted, although  
16 neither was considered necessary by the Department of Fisheries.  
17 Further, the state should be free to negotiate agreements with  
18 the tribe which are of mutual benefit. The department now has  
19 working arrangements or contracts with the Squaxin, Lummi, and  
20 Tulalip Indians regarding salmon culture and sale of fish to the  
21 state. Such efforts might become more important to the tribe  
22 than some aspects of fishing and the tribes should be able to  
23 reach agreements with the state which they see to be in their  
24 best interests.

25 Q. If the court were to adopt the percentage-of-the-harvest method  
26 of defining a fair share for treaty Indian fishing, does the  
27 Department of Fisheries have a data base upon which it could  
28 manage the fishery on that basis?

29 A. Yes, we have. We have all of the standard data and fisheries  
30 statistics. In addition, this material has been analyzed with  
31 special consideration for catches of salmon production from  
32 Indian rivers and a report has been prepared.

33 Q. What is the name of the report that was prepared and by whom was

1 it prepared?

2 A. The report is entitled "Catches of Salmon from Indian Fishery  
3 Rivers of Puget Sound, Coastal Washington and the Strait of  
4 Juan de Fuca" and was prepared by Dr. Steve Mathews.

5 Q. Was Dr. Mathews working under your supervision at the time he  
6 prepared this report?

7 A. Yes, he was biometrician with the Department of Fisheries and  
8 was working on the statistics of the department. He prepared  
9 this report as a part of our regular duties in analyzing all of  
10 the fisheries that we manage.

11 Q. Could you explain what a biometrician is?

12 A. A biometrician is a statistical mathematician who specializes in  
13 the application of mathematics to biological systems and situa-  
14 tions. In the case of Dr. Mathews, he was a fisheries biologist  
15 who worked for the Department of Fisheries for some time and then  
16 returned to the University of Washington for his doctorate in the  
17 mathematical field, so he has years of experience as a fisheries  
18 biologist as well as being a fine mathematician.

19 Q. We will designate this report Exhibit F-6. Mr. Lasater, are you  
20 an expert in the mathematics covered in this report yourself?

21 A. No, I am not, in the sense that I could say that the mathematical  
22 method is the best or only method to be used. I understand the  
23 method used.

24 Q. Are you satisfied, based on your experience as a biologist, that  
25 the method used reasonably portrays the distribution and catch  
26 of salmon from the rivers analyzed?

27 A. Yes, I am satisfied that this document does portray the actual  
28 situation in the fishery so that we can devise management plans  
29 from this data.

30 Q. We move the admission of Exhibit F-6. Would you explain the  
31 method used by Dr. Mathews in his report?

32 A. The first step was to gather together all pertinent data for  
33 analysis. This data would include catch statistics at all levels

1 to determine the harvest and all spawning escapements both to  
2 hatcheries and for wild salmon. Calculation of the distribution  
3 and contribution of the rivers to the various catches required  
4 the use of all data from the case area for contribution and dis-  
5 tribution of marked salmon and tagged salmon. Consideration was  
6 given to any information regarding migration, routes and timing  
7 of the salmon.

8 Q. How does the data from the marked salmon and tagged salmon show  
9 the catch of salmon from a particular river?

10 A. Salmon are marked by placing some identification on them or a fin  
11 clip, excising one fin when they are very small at the time they  
12 are released from a hatchery or migrate to the sea. With careful  
13 allocation of these marks, confusion can be avoided and the  
14 salmon can be traced throughout their life in the marine fishery  
15 wherever caught. Our people sample catches, sport and commercial,  
16 from all of the fisheries that will fish on them, looking for  
17 marked salmon and noting the ratio of marked salmon to unmarked  
18 salmon. Since we can identify these fish as originating at a  
19 particular place and you have the ratio of marked salmon to  
20 unmarked salmon, you can multiply this ratio times the final  
21 catch and determine the origin and number of marked fish that  
22 have been caught in any particular fishery. Tagged salmon differ  
23 from marked salmon in that the former are captured in the rivers  
24 or in the marine areas when they are at a large enough size to  
25 have a tag affixed to them. They can then be identified as they  
26 migrate through the fishery and return to the rivers. Then as  
27 they are captured, you know in which fishery and its location.  
28 In addition, the fishery and the location of capture gives you  
29 the migration routes and timing. Tagged fish which are not  
30 caught in any of the fisheries will escape and can be counted on  
31 the spawning grounds or at hatcheries.

32 Q. From the tagging studies and marking studies, can you determine  
33 which fishery is taking the fish?

1 A. Yes. All the agencies along the coast that manage salmon or  
2 record catches sample for marked fish; therefore, at every land-  
3 ing port of any importance, the salmon landed are sampled to  
4 determine the number of marks in a catch. The actual catches are  
5 also recorded and the numbers of unmarked fish are recorded, as  
6 well as the location of where the fish were caught. This data  
7 can then be analyzed to show the numbers of marks found in each  
8 fishery, the proportion of those marks to the actual catch and,  
9 therefore, the actual contribution of those marked fish to that  
10 fishery.

11 Q. Would it be correct, then, that you could determine on the basis  
12 of your marked and tagged studies what portion of the fish, for  
13 instance, the Canadian fishery might be taken of Puget Sound  
14 origin fish?

1 A. Yes, this has been determined and the figures were used in the  
2 recent negotiations between the United States and Canada. Samples  
3 of salmon caught in the Canadian fishery showed that salmon with  
4 marks originating from the Puget Sound area were very common, in  
5 fact prevalent, in that fishery. This is direct evidence that the  
6 Canadians are intercepting Puget Sound salmon and can be used  
7 directly to determine the numbers.

8 Q. Have marking studies been done on every river analyzed in Dr.  
9 Mathews' study?

10 A. No, they have not. The contribution of some streams has been  
11 judged to be similar to that of other nearby streams where studies  
12 have been performed. For instance, no marked salmon have been  
13 released into the Nisqually River which will return prior to 1974.  
14 However, millions of marked salmon have been released from the  
15 Deschutes River a few miles to the south and from the Minter Creek  
16 hatchery to the west. Young salmon from these three streams must  
17 migrate northward through Puget Sound at the same time and it is  
18 reasonable to assume that they would behave in a similar manner  
19 in the fishery.

20 As mentioned, marking experiments have been begun on the  
21 Nisqually River and if differences become apparent, the data will  
22 be used to update the studies. Such experiments are part of a  
23 continuing effort to improve the data base.

24 Cooperation of Indian tribes is necessary in marked salmon  
25 experiments since the incidence of marks in the Indian catch is a  
26 necessary part of the basic data. In 1971 the Federal Government  
27 contended that the state had no jurisdiction over fishing within  
28 the boundaries of the old Puyallup Reservation. Pending a judicial  
29 determination of the reservation status, the department felt it  
30 was unfair to the Indians to subject them to arrest when the United  
31 States Government was telling them they could fish unrestricted,  
32 so the Department did not enforce its regulations and did not feel  
33 free to sample Indian catches in that area. In that same year, a

1 plant of marked coho salmon was due back in the Puyallup River so  
2 the department asked the Bureau of Sport Fish and Wildlife to get  
3 information on the catches so that the cost and the results of  
4 the experiment would not be wasted. No data was received and  
5 important information was lost.

6 Q. What was the purpose of Dr. Mathews' study?

7 A. Dr. Mathews wished to determine the ratio or the proportion of  
8 the salmon caught from particular rivers by the Indian fishery and  
9 by the all-citizen fisheries in the marine areas wherever they  
10 occurred.

11 Q. If fish are not marked or tagged, is there any way of knowing  
12 whether a particular fish that is caught originated in a par-  
13 ticular stream?

14 A. Not directly, no.

15 Q. Would catch statistics alone then be able to give you the number  
16 of fish originating from a particular stream caught in marine  
17 environment?

18 A. No, they would not because the stocks are mixed.

19 Q. How, then, was Dr. Mathews able to determine the number of fish from  
20 a particular river that was caught in the marine areas?

21 A. It was necessary for Dr. Mathews to derive a calculation by which  
22 he could estimate the number of fish from a particular river in  
23 the marine area. Much of our information about the fish is indirect  
24 because you cannot just walk out and count them. You do sampling  
25 and marking identification studies, so most of the information  
26 is calculated and statistically estimated based on indirect methods.

27 Q. Is the formula on page 2 of Dr. Mathews' report, in which he states  
28 that the  $TMC_{ij}$  is equal to  $R_{ij}$  times the sum of  $E_{ij} \div H_{ij} \div$   
29  $F_{ij} \div I_{ij}$ , a formula to determine the number of fish caught in the  
30 marine environment of a particular species from a particular river?

31 A. Yes, it is. The symbols are identified on p. 2 of Dr. Mathews'  
32 report. The  $TMC_{ij}$  is the total marine catch of a particular  
33 species from a particular river and is the product of the equation.

1  $R_{ij}$  is the average ratio of the all-citizen marine catch to the  
2 return to the river. It is derived from marked fish studies,  
3 primarily, and any other pertinent data, whereby the number of  
4 fish caught in the marine area from identifiable fish can be com-  
5 pared to the actual observations of fish bearing such a mark which  
6 return to the river. This ratio is multiplied times the sum of  
7 1) the average annual escapement of the species to the river which  
8 is derived from index counts in spawning areas; 2) the average  
9 annual hatchery escapement of the species where it is applicable  
10 by actual counts at our hatchery racks; 3) the average annual river  
11 sport catch of the species in that river derived from punch cards;  
12 and 4) the average annual Indian fishery catch of the species in  
13 that river derived from the fish tickets that are received from  
14 the sales of those fish. These last figures reflect the Indian  
15 commercial catch. Thus, Dr. Mathews' figures do not include the  
16 Indian personal-use catch, nor do the calculated percentage shares.

17 Q. When you say average annual, what period of time are the figures  
18 in this report averaged over?

19 A. Six full years of natural escapement data were used as the base  
20 years. 1965-1970 was used in terms of estimates for chinook,  
21 coho, chum and sockeye salmon. Pink salmon, which run only every  
22 other year in Puget Sound, were compared over six odd-year cycles  
23 from 1959 to 1969.

24 Q. Would the figures for the average annual natural escapement count,  
25 hatchery escapement count, river sport catch count, and Indian  
26 fishery catch count be based on actual counts made of those fisher-  
27 ies for escapements?

28 A. Yes, each count is based upon physical counts or physical report-  
29 ing of the catch, such as somebody weighing and counting the fish  
30 and putting them on a fish ticket and sending that information to  
31 the department.

32 Q. Could you give us an example of how this formula might work in  
33 determining the total marine catch from a particular species of a

1 particular river?

2 A. For instance, if the ratio of marine catch to the river return,  
3 as found by tagging and marking studies, was 2:1, then for every  
4 salmon that returned to the river, two are caught in the ocean.  
5 If the return of salmon to the river was 5000 chinook, as deter-  
6 mined from the actual counts of the river fisheries and escapements,  
7 the ocean catch of salmon from that river would be estimated at  
8 10,000 salmon.

9 Q. Did Dr. Mathews then break down the marine catch into the catches  
10 of specific fisheries in marine areas?

11 A. Yes, he did. It is important to know where the fish are caught,  
12 which fisheries catch them, and in what numbers in order to  
13 manage the fishery.

14 Q. What was the basis of his determination as to the breakdown of  
15 the catch to specific marine fisheries?

16 A. The marked fish, tagged fish studies, once again, will show the  
17 ratio of the catch of fish of that particular mark in the particu-  
18 lar fisheries. With enough of these studies, then, one can get a  
19 pretty good idea of the distribution of catch from the various  
20 areas and rivers of Puget Sound into the various fisheries in the  
21 marine areas.

22 Q. What then was the sum product of the analysis of Dr. Mathews?

23 A. His final product is a series of figures which show the distribu-  
24 tion of the catch and the return to a number of important rivers  
25 in Puget Sound. These figures will show the Indian catch, the  
26 river sport fishery catch, the hatchery spawning escapement, and  
27 the wild spawning escapements as their total return to the river.  
28 It will show the distribution of the marine catch from that river  
29 in such areas as the California troll fishery, the British Columbia  
30 troll fishery, the Washington troll fishery, Oregon troll fishery,  
31 sport fisheries in British Columbia, Washington and Oregon, the  
32 net fisheries in Canada and the Strait of Juan de Fuca, net fisher-  
33 ies Johnson-Georgia Strait area in Canada, the Washington net

1 fisheries in outer Puget Sound, inner Puget Sound and the sport  
2 fishery in Puget Sound.

3 Q. Has your department prepared exhibits showing the distribution  
4 of the catch from rivers upon which there are Indian fisheries?

5 A. Yes, we have.

6 Q. Were these exhibits prepared on the basis of the figures contained  
7 in Dr. Mathews' report in Tables 1-27?

8 A. Yes they were.

9 Q. We will mark these exhibits as follows and move their admission:

10 Exhibit F-7 Estimated Catch and Escapement of Salmon  
11 Originating from Several Puget Sound and  
12 Coastal Rivers on which Indian Fisheries Occur.

13 Exhibit F-8 Estimated Catch and Escapement of Salmon  
14 Originating from the Hoh River.

15 Exhibit F-9 Estimated Catch and Escapement of Salmon  
16 Originating from the Hoko River.

17 Exhibit F-10 Estimated Catch and Escapement of Salmon  
18 Originating from the Nisqually River.

19 Exhibit F-11 Estimated Catch and Escapement of Salmon  
20 Originating from the Nooksack River.

21 Exhibit F-12 Estimated Catch and Escapement of Salmon  
22 Originating from the Puyallup River.

23 Exhibit F-13 Estimated Catch and Escapement of Salmon  
24 Originating from the Quillayute River.

25 Exhibit F-14 Estimated Catch and Escapement of Salmon  
26 Originating from the Skagit River.

27 Exhibit F-15 Estimated Catch and Escapement of Salmon  
28 Originating from the Skokomish River.

29 Exhibit F-16 Estimated Catch and Escapement of Salmon  
30 Originating from the Snohomish-Stillaguamish Rivers.

31 Exhibit F-17 Estimated Catch and Escapement of Salmon  
32 Originating from the Southern Puget Sound.  
33

- 1 Q. Would you please describe the Exhibits F-7 to F-17.
- 2 A. Exhibit F-7 shows calculations of the distribution of the average  
3 annual catch from a composite of the Hoko, Quillayute, Hoh,  
4 Skokomish, Southern Puget Sound streams, Nisqually, Puyallup,  
5 Snohomish, Stillaguamish, Skagit and Nooksack Rivers. Exhibits  
6 F-8 to F-17 show the catch distribution for particular rivers.  
7 Included for each is the spawning escapement and the amount of the  
8 catch taken within three miles of the coast or within state juris-  
9 diction and that taken outside of three miles.
- 10 Q. The tables and figures show a great variation in spawning escape-  
11 ment. Can you explain this?
- 12 A. Yes. The biology of the salmon is a major factor. Among other  
13 things, Pink and chum salmon go to sea as small fry and rearing  
14 space in the river is not a limiting factor, but mortality at sea  
15 is high. These salmon require that a large part of the run  
16 escape to spawn. On the other hand, fall chinook rear in the  
17 river for about 120 days, so their mortality at sea is less and  
18 few spawners are needed. Coho rear in the river for a full year  
19 but their numbers are limited by rearing space in the stream  
20 during the summer low flows. Further, a Pink salmon will carry  
21 about 2,000 eggs, a Coho about 3,000 eggs, and a chinook salmon  
22 about 5,000 eggs with corresponding spawning requirements. The  
23 character of the river is also important. For instance, a river  
24 which has a limited spawning area for coho but a great deal of  
25 rearing area can be cropped heavily. In some cases we rely on  
26 experience alone to know that a particular escapement produces  
27 the maximum run from a river.
- 28 Q. What do the tables in Exhibits F-7 to F-17 show about the fisheries  
29 on the stocks and rivers indicated?
- 30 A. The table in Exhibit F-7 for the aggregate of the several rivers  
31 will provide an understanding of all the tables in Exhibits F-7  
32 to F-17. First, for chinook salmon the greatest part of the catch  
33 is taken outside of state jurisdiction. Of the catch within state

1 jurisdiction, Indians take 7.8% of the total runs while the all-  
2 citizen fishery takes 18.8%. Second, for coho the major part of  
3 the catch also comes in waters outside the state jurisdiction.  
4 Within state jurisdiction, Indians take 7.8% of the runs and the  
5 all-citizen fishery takes 17.9%. Third, for pink salmon, over half  
6 of the catch is taken outside of state jurisdiction, and within  
7 state jurisdiction Indians take 8% and the all-citizen fishery  
8 takes 25.9% of the run. Much of the Pink salmon catch is taken  
9 under the management of the International Pacific Salmon Commission.  
10 Fourth, few chum salmon are taken outside of state jurisdiction  
11 since very few take lures or bait in ocean waters. Indians take  
12 19% of the total run and non-Indians take 24%.

13 Q. What conclusions do you draw from Dr. Mathews' report and the  
14 tables in Exhibits F-7 to F-17?

15 A. First, with chinook, coho, and Pink salmon, a great portion of  
16 the catch is taken in international waters which are not under  
17 jurisdiction of the state. Secondly, the Indian fishermen take  
18 a significant percentage of the salmon from these rivers especially  
19 when compared with the all-citizen catch within state jurisdiction.  
20 Further, data so compiled and analyzed forms a basis for calculating  
21 and managing a fair share of the catch for treaty Indian fisheries.

22 Q. Earlier in your testimony you indicated that the United States, in  
23 negotiating with Canada this year regarding the interception of  
24 salmon from one nation by the fishermen of another nation, con-  
25 tended that Canadian fishermen were taking approximately 83% of  
26 Puget Sound chinook salmon and approximately 65% of the Puget Sound  
27 coho salmon. Were these percentages derived by calculations  
28 similar to those performed by Dr. Mathews in his report?

29 A. Yes, the calculations were derived in the same way and from, in  
30 great part, exactly the same marking and tagging studies. The  
31 material derived for the Canadian catch, in fact, was part of these  
32 same calculations. Now, I think it is significant that the Canadian  
33 scientists also agree within a very close margin with these salmon

1 figures based upon their analysis of the same fisheries with  
2 basically the same marking and tagging information.

3 Q. Would you say, then, that the methods used by Dr. Mathews have  
4 found general acceptance among fishery managers on the Pacific  
5 coast?

6 A. Yes, these methods are in general use, and Dr. Mathews is well  
7 known to other fishery managers along the coast and has a good  
8 reputation among them and with the College of Fisheries at the  
9 University of Washington where he now works.

10 Q. In addition to the study performed by Dr. Mathews, does the  
11 department have any other studies which it has prepared which  
12 would assist it in managing the fishery under a percentage share  
13 basis?

14 A. Yes, we have a report entitled "Salmon Escapement and Desired  
15 Escapement Levels to Certain Puget Sound Systems Containing  
16 Indian Fisheries" prepared by the Washington Department of  
17 Fisheries staff and dated March, 1972.

18 Q. We will identify the study you have just referred to as Exhibit  
19 F-18. Was this exhibit prepared under your over-all direction  
20 and supervision?

21 A. Yes, it was.

22 Q. Have you reviewed this study on salmon escapement and desired  
23 escapement levels?

24 A. Yes, I have.

25 Q. Based on your experience as a fish biologist, would you say that  
26 the information contained in this study truly portrays actual  
27 escapement and desired escapement to the river systems studied?

28 A. Yes, I do.

29 Q. We move the admission of Exhibit F-18.

30 In examining the tables contained in Exhibit F-18, it is often  
31 the case that the actual escapement levels do not meet the desired  
32 minimum escapement goals. Can you explain why there are these  
33 discrepancies?

1 A. Yes, the people responsible for preparing these tables are  
2 assigned to managing the fresh-water portion of the system - the  
3 escapement. Their job is to determine what is best for the fish.  
4 It is not their job to determine what's best for human beings and  
5 the fishermen and the catching and using of the resource. There-  
6 fore their goals are idealistic when you consider that in a fish-  
7 ery you are managing the catch and the fishery species for the  
8 benefit of the human race and not for the fish species involved.  
9 For example, this year we are expecting a very small run of  
10 chinook salmon back to Puget Sound. We have set seasons which  
11 close the commercial fishery and curtail the sport fishery on this  
12 run. Even so, we are doubtful in some cases that spawning  
13 escapements will be met. On the other hand, we have predicted a  
14 very good run of coho salmon to Puget Sound. Now when the coho  
15 arrive, the last portion of the chinook salmon run will still be  
16 in fishing areas. To say that all of the chinook salmon should  
17 be saved would require foregoing a very good silver salmon harvest.  
18 This is not in the interest of the State of Washington or of  
19 conservation of the coho salmon stock.

20 Q. Would the desired minimum escapement goals indicated in those  
21 tables be used by the department to diminish the fair share of  
22 the harvest for Indians?

23 A. No. Under a percentage fair share any plan of the Department of  
24 Fisheries to increase the spawning escapement to a particular  
25 river would require that restrictions be placed upon both fisher-  
26 ies to meet that goal; otherwise the fair share idea is violated.  
27 If we allow the all-citizen fishery more salmon, then we owe a  
28 percentage to the Indian fishermen--so we would want to treat them  
29 both the same to avoid a debit to the Indians that would have to  
30 be made up that year or the next.

31 Q. How would hatchery production apply to treaty Indian fisheries?

32 A. Standard hatchery plants which have been made over the years and  
33 which are regularly scheduled would be included in productivity

1 over and above natural production. As the hatchery production of  
2 the state increases, plants of salmon to treaty Indian fishing  
3 areas would increase. Hatchery plants to rivers with Indian  
4 fisheries are a routine matter with the Department of Fisheries,  
5 as illustrated by Table 29 in the Joint Biological Statement  
6 prepared for this case.

7 Q. Would the productivity base change from time to time and, if so,  
8 what would be done?

9 A. The base will be revised upward or downward as new information is  
10 made available and will be re-evaluated every 5 years in any case.  
11 The data base is not perfect and may never be since the world  
12 constantly changes. Further, rivers may change or be changed and  
13 production altered accordingly. If the Stream Improvement Division  
14 builds a fish ladder to make an area above a falls available to  
15 salmon, the productivity of the stream increases. If a slide  
16 destroys spawning area, productivity decreases. Changes in marine  
17 waters affecting survival also affect productivity.

18 Q. What will be done if more data is needed to refine calculations  
19 of productivity?

20 A. Special studies will be made to acquire the data. Department of  
21 Fisheries staff is steadily involved in such work since it is  
22 needed for many purposes. The techniques are known, and a number of  
23 projects scheduled for the 1973-1975 biennium are of this nature  
24 and affect the case area. In committing itself to a fair share  
25 for Indians, the Department of Fisheries will be committed to  
26 establishing a sound basis for its management program. Just as  
27 an example of what is being done, this year alone the department  
28 expects the return of eleven million tagged or marked fish.

29 Q. Suppose new runs of salmon are established, how might the Indians  
30 share in these?

31 A. As soon as such runs are established to the point that they can  
32 support a fishery in the usual and accustomed area, such runs will  
33 be added to the base and a share established for treaty Indians.

1 Some species and races of salmon are particularly attractive for  
2 adaptation to Indian river fisheries. Spring run chinook salmon,  
3 for example, run when salmon are relatively scarce and are of  
4 excellent quality in river fisheries. Not only would they supply  
5 subsistence when salmon are scarce, but the market price would be  
6 high.

7 Q. Is the Department of Fisheries now working toward the establishment  
8 of such runs?

9 A. Yes. With thoughts of both the sport fishery and the Indian  
10 fishery, we are now selecting strains of salmon and testing hybrids  
11 which will contribute to the fishery early in the year, have a  
12 higher quality in river fisheries, and which can be managed separately  
13 from the all-citizen commercial fishery. One of these is  
14 the hybridization of Puget Sound chinook salmon with the Rivers  
15 Inlet stock from British Columbia. Another example is rearing  
16 experiments using the remnant stock of spring chinook from the  
17 Puyallup River system.

18 Q. How will salmon taken on an Indian reservation count in reckoning  
19 a fair share?

20 A. Salmon taken on a reservation will not be counted as part of the  
21 fair share unless they are transported off the reservation and sold.  
22 Personal-use salmon will not be counted as a part of the fair  
23 share. I have heard it said for many years in the Department of  
24 Fisheries that if the Indian fishery was for personal use, any  
25 problems would be of a minor nature. On the other hand, the  
26 department is willing to count the sport catch as part of the all-  
27 citizen harvest in establishing a share.

28 Q. Why are commercial reservation catches to be included in calculating  
29 the Indian fair share catch?

30 A. There are a number of reasons.

- 31 1. The reservation catch on a stream could be increased to the  
32 point that it took the entire harvest and the state would  
33 still owe the Indians a share which it could not possibly

1 deliver...

2 2. Catches taken off-reservation would be taken to the reservation  
3 and sold from there, or simply reported as being taken on the  
4 reservation at the time of sale. There would be little chance  
5 of proving otherwise and the fishery would be unmanageable.

6 3. There would be an incentive to over fish, which the state could  
7 not control, and spawning escapements would suffer. As the run  
8 diminished, accordingly the productivity of the river would be  
9 reevaluated downward and the calculated fair share diminished.  
10 Salmon management would suffer, the Indian share would suffer  
11 and relations between the state and the Indians would be  
12 impaired.

13 4. Indians with a reservation would have a great advantage over  
14 those without. The treaty fishery would then have different  
15 values for different treaty tribes, which is not fair on the  
16 face of it, and relationships between the tribes and the state  
17 and the tribes would suffer.

18 Q. You have stated that Indians would share in any increase in the  
19 productivity of a river. Are there any examples where such has  
20 already occurred?

21 A. Yes, there are a number of examples. Fall-run chinook are not  
22 native to the Skagit River and plants of these fish from the  
23 Skagit Hatchery now regularly augment the Swinomish Indian catch.  
24 Hatchery plants have held up the catches of the Lummi Indians from  
25 the Nooksack River. Their catches would be very low without  
26 hatchery augmentation. The Skokomish Indians have had a great  
27 increase in their chinook catch, as is shown in Exhibit F-19. In  
28 addition, they have been encouraged by the department to fish harder  
29 on the hatchery portion of the coho run.

30 Q. We will submit Exhibit F-19.

31 Does the Department of Fisheries furnish salmon to Indian tribes?

32 A. Yes. Certain of the salmon arriving at hatcheries are not needed  
33 or are not desirable as spawning stock. The early arrivals in a

1 run often will not ripen properly, yet are in the best condition  
2 of any for fresh or canned use. The department plans for some  
3 extra salmon, rather than fall short of spawning needs, and needs  
4 some extra fish so that only the best fish are used for propagation.  
5 The milt from one male salmon will fertilize the eggs from several  
6 females, thus many males are surplus in artificial propagation.  
7 Finally, in many cases salmon which have been spawned are quite  
8 edible and in fact make a superior hard-smoked product. Salmon,  
9 as described, have been made available to Indian tribes for a  
10 number of years. A listing of these and the considerable amounts  
11 taken are shown in Exhibit F-20.

12 Q. We will submit Exhibit F-20.

13 Would such salmon count as part of the fair share?

14 A. Such salmon would not count unless they were sold and thus put in  
15 commercial channels. Otherwise, they would fall in the same  
16 category as personal-use fish.

17 Q. Do the Indians value such salmon?

18 A. Yes. The department receives requests from a majority of tribes  
19 and arranges for a way for older Indians and non-fishing Indians  
20 to get fish for their use. It is also a source of food for the  
21 poor. For example, a few years ago I met with the leaders of the  
22 Suquamish tribe on their reservation at the home of Mrs. George.  
23 They told me that the tribe did not wish to encourage Indians to  
24 fish for salmon in the small streams near their reservation, but  
25 salmon were a part of their diet and they wished to continue to  
26 eat salmon. They made it known to me that they wanted some salmon  
27 from the early part of the run in bright condition for fresh fish  
28 and canning and some salmon at near spawning time for smoking.  
29 Salmon have been made available to the Suquamish tribe as a result  
30 of that meeting.

31 Q. What unit will be used in calculating the fair share?

32 A. The share will be calculated in numbers of salmon by species.  
33 Salmon are accountable in numbers and such a system is manageable

1 and fair. If salmon are protected by regulation in an all-citizen  
2 fishery and have a lower value in an Indian harvest in the river,  
3 there should be no penalty for the people who were prohibited from  
4 catching them when of a higher value. If Indians catch spring  
5 chinook which are of high value in a river, the value should not  
6 be counted against them either. The department will have as a  
7 goal, management of Indian fisheries to achieve the highest value  
8 consistent with the species of salmon and the location of the  
9 Indian fishery.

10 Q. Will Indians have an opportunity to catch their fair share of  
11 salmon when it is of a higher value?

12 A. Yes, Indians can participate in the all-citizen fishery.

13 Q. Do you believe that accounting by number rather than value satisfies  
14 the treaty right?

15 A. Yes, at treaty times the greatest proportion of the Indian catch  
16 was in rivers where values on the average are lower in today's  
17 non-Indian market place. Further, even though the trading of  
18 salmon was common, the bulk of the catch was used for subsistence.  
19 The Indian people, in private conversation, public hearings and  
20 court cases have stressed the importance of salmon for subsistence.

21 Q. Is it necessary to regulate a personal-use fishery?

22 A. Yes. Some areas, such as spawning areas, should not be fished at  
23 all for conservation reasons. Regulations are also necessary to  
24 prevent abuses which would affect the resource or other fisheries.  
25 But a personal-use fishery does not have to be as restrictive as  
26 a commercial fishery. As I indicated earlier, we are willing to  
27 set up personal-use seasons for Indians.

28 Q. How would you consider salmon caught by treaty Indians if they  
29 were commercial fishing in areas open to all citizens?

30 A. The Indians would have a choice in that case. If an Indian fished  
31 under treaty right, he would get a free license and would not be  
32 required to pay landing taxes on his catch. Any salmon sold would  
33 be included in the fair share. He could, on the other hand, buy

1 a commercial fishing license, pay the taxes, and obey all the  
2 regulations pertaining to non-Indians and his catch would count as  
3 a portion of the all-citizen catch.

4 Q. How would the Department of Fisheries identify treaty Indian  
5 fishermen?

6 A. There is a problem in knowing whether a person is an Indian and  
7 specifically a treaty Indian. Further, the treaty right is a  
8 tribal right and not an individual right. The Department of  
9 Fisheries would depend upon the tribes to furnish to the State a  
10 list of people from that tribe eligible to fish. We believe that  
11 the tribes will guard the treaty right and would not include people  
12 on the list who should not fish as tribal members. In addition,  
13 by relying on the tribe the state would not stand between the  
14 tribe and its members in exercising any authority they may have  
15 in regulating their people.

16 Q. I am now drawing your attention to methods for managing the fish-  
17 eries to ensure a fair share for Indians. Is it expected that the  
18 Indians will catch exactly their share in any given year?

19 A. No. Management is not that precise and, even if it were, regulations  
20 would have to be extremely dictatorial to achieve exact figures.

21 Q. If variation is to be expected, how will Indians be assured of  
22 their fair share?

23 A. The fair share is to be accountable annually and may show a credit  
24 or a debit which will be carried over to the next year. A balance  
25 will be drawn every 5 years as a measure of performance. Any debit  
26 found at that time will still be owed to the Indians.

27 Q. Since there are several species of salmon of different values, how  
28 will these be accounted for?

29 A. The share will be calculated by each species so that treaty Indians  
30 will get a share of all species native to their fishing areas. If  
31 during the fishing year it is apparent that the fair share of one  
32 species is not going to be met, the department will have the right  
33 to make it up by increasing the catch of other species. In this

1 case, value must be taken into account. It would not be fair to  
2 equate a 20 lb. chinook salmon at a higher price with a 6 lb. chum  
3 salmon at a lower price. If one species is to be substituted for  
4 another, an equivalence in values based upon prices received by  
5 Indian fishermen would be necessary.

6 Q. Would such balancing-out during the season always be possible?

7 A. No. For example, if the deficit occurred on a very large run of  
8 one species of salmon and the runs following are weak, it might  
9 be biologically impossible to make up the difference in that year.

10 Q. If in a particular year the Indians do not catch a fair share,  
11 what is to be done?

12 A. Any imbalance is to be adjusted in the following year. A deficit  
13 will require that the all-citizen fishery be curtailed further to  
14 increase the Indian catch. A credit would be made up by increasing  
15 the all-citizen fishery relative to the Indian fishery.

16 Q. Suppose that a chronic deficit develops in an area due to some  
17 management difficulty?

18 A. Specific increases in the planting of hatchery fish will be made  
19 to bring the catch up. Such plants would be over and above standard  
20 scheduled releases which are counted as part of the productivity of  
21 the system.

22 Q. Is the cooperation of the treaty tribes necessary to ensure a  
23 fair share?

24 A. Yes, and, in addition, to ensure conservation of the resource. As a  
25 part of the necessary data base, the treaty tribes should furnish  
26 catch and fishing effort information to the Department of Fisheries  
27 concerning reservation landings. Salmon catch management comprises  
28 three parts: run size, catch, and escapement. Both fair share  
29 and escapement ensurance require good current information concern-  
30 ing catch. Doubt as to the size of the catch causes a manager to  
31 set conservative seasons to protect the escapement and more  
32 emergency closures become necessary. Advances and improvements in  
33 management depend upon a sufficiency of correct data. Suppose that

1 two strains of salmon have been planted in a river and each group  
2 has an identifying mark so that their relative survivals can be  
3 assessed. A lack of catch data and marked salmon information will  
4 cause the experiment to fail with a waste of manpower and materials.  
5 Further, future catches will not benefit from the selection of a  
6 superior stock of salmon. One has but to scan the table of contents  
7 of the Joint Statement to see that the vital statistics of the  
8 salmon is a basic requirement for anyone engaged in management.

9 Q. Suppose that more than one tribe fishes a given river; how is the  
10 fair share to be divided among the tribes?

11 A. The Department of Fisheries has no basis for dividing the catch  
12 between individual Indians or tribes or bands thereof. At the  
13 time of the signing of the treaty and before, I assume that the  
14 Indians decided matters of fishing areas and catches in some manner.  
15 Situations will arise where fishermen from several tribes will fish  
16 the same area unless other arrangements are made. In other cases,  
17 one tribe fishes the lower reaches of a river and another tribe  
18 fishes further upstream. For instance the Puyallup Indians fish  
19 downstream from the Muckleshoot Reservation. The Muckleshoot  
20 Indians are dependent upon sufficient salmon escaping the Puyallup  
21 fishery to provide for a reservation catch.

22 Q. Do you know of any instance where Indians regulate their members  
23 to avoid conflict or over-harvest due to competition for salmon?

24 A. Yes, the Quinault, Hoh and Quillayute Indians are under the same  
25 treaty but have agreed that the people who live on the river shall  
26 fish that river and shall not fish upon the other rivers.

27 Q. How will the state responsibility for ensuring a fair share be  
28 accounted for, if not by tribe?

29 A. The accounting will be based upon the productivity of the rivers  
30 and streams and the total catch of treaty Indians therefrom.  
31 Jurisdictional disputes or arrangements are to be settled by the  
32 tribes as Indian business, and the Department of Fisheries would  
33 honor agreements made where practical and the needs of conservation

1 were met.

2 Q. How does the all-citizen fishery affect the fair share for treaty  
3 Indians?

4 A. Due to geography and salmon migrations, the all-citizen fishery,  
5 with some exceptions, takes place prior to the Indian fishery.  
6 The all-citizen fishery must then be regulated with sufficient  
7 accuracy that salmon escape to supply an Indian catch and proper  
8 escapement.

9 Q. Do you forecast the strength of salmon runs?

10 A. Yes. Predictions are made for each species. Counts of salmon on  
11 the spawning grounds show the potential egg deposit for the next  
12 generation. As the eggs develop samples are taken to determine  
13 the survival of both eggs and fry. Survival to fingerling or  
14 migration stage is determined directly by observation or by measure-  
15 ing factors that determine survival. For instance, river flow  
16 during their fresh water existence is directly related to coho  
17 abundance. In some cases, acoustical surveys are made to determine  
18 the abundance of young sockeye. While this accounting is not  
19 exhaustive it is indicative of the methods used. Further refine-  
20 ments and new techniques are being developed year by year.

21 Q. Are forecasts based upon the abundance of your salmon refined at  
22 a later date?

23 A. Yes. As salmon enter the fisheries, their abundance is noted as  
24 well as the timing of the run, whether early, normal or late. Catch  
25 per unit of effort is analyzed, as well as total catch, and compared  
26 with the data and experience of past years to determine run size.  
27 New estimates are made as often as they are needed for management,  
28 most often on a weekly basis but at times from day to day in  
29 critical situations.

30 Q. How are salmon runs protected from over harvest when the runs from  
31 a number of rivers are mixed together?

32 A. Predictions will show the expected strength of a particular species  
33 in general, and regulations will set a generous season if a large

1 run is expected, and fewer days if a smaller run is the case. In  
2 such areas it is common to have three days per week of fishing.  
3 Thus, four days are closed and salmon migrate from the areas where  
4 all are mixed to areas where fewer runs are involved. Fishing  
5 times then may be either increased or reduced depending on the  
6 relative strength of the stocks remaining. Finally, as salmon  
7 approach a particular river, regulations can be specific for that  
8 stock even though some salmon bound for other rivers are still  
9 present. For example, we have in the past asked the Lummi Indians  
10 to increase their fishing effort on the hatchery-produced chinook  
11 run in the Nooksack River for the reason that we could not increase  
12 the harvest in marine areas where stocks are mixed, and it was  
13 necessary to restrict fishing to protect runs migrating to other  
14 rivers. The same has been true with the Skokomish Indians on  
15 the Skokomish River.

16 Q. Will you explain how a salmon run is managed as it enters the net  
17 fisheries of Puget Sound and proceeds to southern Puget Sound?

18 A. The first fishery entered will be a gill net fishery in the outer  
19 Strait of Juan de Fuca. Few purse seines fish there due to  
20 adverse conditions. Near Discovery Bay purse seines become impor-  
21 tant in the fishery. If these waters are under control of the  
22 International Salmon Commission, as they are during most or all of  
23 the summer, regulations are basically for the management of Fraser  
24 River pink and sockeye salmon. Salmon bound for Puget Sound may  
25 be either over or under harvested at that point. The state often  
26 requests special consideration for the protection of Puget Sound  
27 stocks. In Admiralty Inlet along Whidbey Island, salmon from Hood  
28 Canal and the Snohomish, Stillaquamish and Skagit Rivers are mixed  
29 with southern Puget Sound salmon. Closure lines are often drawn  
30 here since salmon bound for streams to the east will tend to be  
31 more prevalent along the Whidbey Island shore. The remaining  
32 stocks bound for Lake Washington and streams to the south are  
33 managed as a unit until they near Tacoma. Here a part of East Pass

1 is closed for the protection of salmon bound for the Puyallup  
2 River even though salmon bound for streams further south such as  
3 the Nisqually River, the Deschutes River and Minter Creek are  
4 present. Any Nisqually River salmon so protected will enter the  
5 Nisqually Indian fishery. Measures to protect other runs have  
6 produced excess escapements to Minter Creek which has a hatchery.  
7 Here special seasons with a limited number of vessels are managed  
8 to take any excess. The artificial run at the Deschutes River has  
9 not required special management to date. The salmon preserve  
10 extending southward from Fox Island south of Tacoma is closed to  
11 commercial fishing except for special fisheries such as at Minter  
12 Creek and the Squaxin Indian treaty fishery. If the Nisqually  
13 Indian fishery did not exist such a large preserve would not be  
14 required.

15 Q. Is the principle of managing the all-citizen fishery to provide  
16 an Indian take new to the Department of Fisheries?

17 A. The Department of Fisheries has in my memory always found it  
18 necessary to take into account Indian reservation fisheries and  
19 regulated other fisheries accordingly. The first priority is  
20 protection of the spawning escapement, and the Indian reservation  
21 catch must be estimated in advance and allowed for. Since the  
22 Puyallup decision, off-reservation fisheries have been established  
23 and more restrictive regulations have been necessary to accommodate  
24 them for the reasons that I discussed earlier.

25 Q. Is the management task ended when salmon have been <sup>en</sup>ensured for the  
26 Indian fishery?

27 A. No, since spawning escapement must still be <sup>en</sup>ensured, regulation of  
28 the Indian fishery is necessary.

29 Q. Under a fair share what will be the management goals of the Depart-  
30 ment of Fisheries in regulating the fisheries?

- 31 A. 1. Ensure that there is sufficient spawning escapement.  
32 2. Meet the fair share requirement for treaty Indians.  
33 3. Manage the all-citizen fishery in the best interest of the State

1 of Washington.

2 Q. If a fair share is established would a management plan emerge  
3 immediately in its final form?

4 A. Not in its ultimate final form, no. But we would begin to manage  
5 according to the percentage share model I have been discussing.  
6 An extension and modification of present management techniques  
7 would give us a good workable beginning. However, new data and  
8 experience generated both by the department and Indian fishermen  
9 could be expected to be used to improve management. I would  
10 expect the greatest variance from desired goals to occur during  
11 the first 5 years of operation. As explained earlier, variances  
12 in catch would be made up on the following years. If escapements  
13 are impacted, hatchery plants will be used to augment runs.

14 Q. The use of a trap at each river mouth has been proposed as a means  
15 to manage salmon precisely and economically. Theoretically,  
16 how would such a trap be established and operated?

17 A. No other fisheries would exist, and the trap would capture all of  
18 the salmon returning to the river. The precise number needed for  
19 escapement would be placed upstream and all others harvested.

20 Q. Do you have experience which would relate to the construction,  
21 maintenance and operation of such a trap?

22 A. Yes. I have observed the construction and operation of conventional  
23 salmon traps such as those operated by the Swinomish Indians. A  
24 dam with fishways operates as a controlling device, and salmon are  
25 easily led from a fishway to a trap or enclosure much as the  
26 department facilities are operated at the Tumwater fishways.  
27 Hatchery racks are intended to stop a salmon run so that salmon  
28 are taken for spawning and others put upstream for natural spawning.

29 Q. Under actual operating conditions is such a trap feasible from a  
30 physical operating standpoint?

31 A. No, it is not. The experience with conventional salmon traps does  
32 not apply since they are fishing devices and are not designed or  
33 intended to capture all of the salmon or stand up to the entire

1 flow of a river. The trap would have to control all of the width  
2 and depth of the river at the greatest flows which would occur  
3 during salmon runs. Floods could be expected to endanger, damage  
4 and destroy the trap. The trap would not only have to resist water  
5 flow but the shock or impingement of any logs and debris brought  
6 down. I was working at a salmon barrier and trap on the Baker  
7 River one night when the river went from summer low to extreme  
8 flood in a matter of hours and blew out a well-constructed facility  
9 made of heavy timbers. A year ago this winter the Engineering staff  
10 of the department dynamited the hatchery rack at the Green River  
11 Hatchery to alleviate flooding and to save the rest of the facility.  
12 That rack is on Soos Creek which is normally a minor stream.

13 Q. Would salmon be protected and controlled by such a structure?

14 A. No. Salmon generally delay at such a structure before finding or  
15 attempting to enter a fishway or trap. Such a delay uses time and  
16 energy intended for migration and spawning. After sufficient  
17 salmon are taken for spawning, hatchery racks or a portion thereof  
18 are generally removed to allow unimpeded passage. Chum salmon, in  
19 fact, may refuse to use a fishway at all. During floods and high  
20 water, damage to the structure is most likely and salmon passage  
21 and trap facilities most difficult to control. Salmon migration  
22 peaks in most rivers during high water. Our experience with weirs  
23 placed in rivers for the enumeration of salmon runs first causes a  
24 delay in migration and then a blow out on high water and the salmon  
25 escape freely.

26 Q. Have you looked into the cost of a trap which would completely  
27 control catch and escapement?

28 A. I have asked the Engineering staff of the department for estimates  
29 of the magnitude of the task and costs for a large river, the  
30 Skagit, a medium sized structure such as the hatchery rack on the  
31 Kalama River, and a small structure such as the hatchery rack on  
32 Soos Creek. On the Skagit River the unit would be composed of  
33 the following:

1. A barrier incorporating a drop of 8 feet completely across the river.

2. Fish ladders and capture and sorting devices on each shore.

3. Two residences for permanent crew.

4. Upstream safety device for small boats.

5. Access roads.

Such a system would not cost less than 6 million dollars. Once completed, operation and maintenance must be scheduled. This would require the following:

1. A minimum of 6 people full time.

2. Debris handling by 4 men plus equipment.

3. Security on a 24-hour basis to prevent poaching.

Even so, with the best design known salmon would delay from 2 to 4 days before entering the fishways.

The hatchery rack on the Kalama River is not kept in the river year-round. On those years when floods have come early while we were still trapping salmon, major damage has occurred. This rack is 249 feet long and when in operation requires three men full time, a mobile home at the site, and a tank-hauling truck. The cost of replacing this rack would be approximately \$160,000.

Q. Would you expect legal problems?

A. Yes. The control of river flows in any way affects property, and experience would lead us to expect legal difficulties. Further, the blocking of a navigable stream is a Federal matter and might require the additional cost and operation of a marine railway. Locks do not work since they readily pass salmon as well as boats.

Q. Would a trap really allow precise management?

A. No. In order to know precisely how many salmon to harvest, the run size of each species must be precisely known. With no preceding fishery there could be no refinement of the original estimates. A test fishery with a controlled fleet to assess the run size as it approached through Puget Sound would require such an array of vessels that we might as well let the fleet operate. Further,

1 test fishing is not precise unless it works on unmixed stocks.

2 In my estimation, a test-fishing fleet would have to operate  
3 continually in the vicinity of the river mouth. In summary,  
4 either precise information on run size will be lacking or the test  
5 fishing fleet will approach the scale of an independent fishery.

6 Q. Would you expect controlling traps to be acceptable to fishermen?

7 A. No. A single agency, presumably governmental, would operate the  
8 trap. The catch would be portioned out under some allocation plan  
9 to those individuals entitled to salmon. Such an operation is  
10 contrary to the traditions and culture of United States citizens,  
11 Indian and non-Indian alike. I cannot believe it to be compatible  
12 with a treaty right to fish in usual and accustomed places.

13 Q. Let's turn our attention to procedures for regulating and managing  
14 Indian treaty fisheries. How would the Indians be able to  
15 express their viewpoints?

16 A. Indian fisheries will be accorded a separate regulation hearing,  
17 as the commercial and sport fisheries are now regulated. Previ-  
18 ously, Indian off-reservation fishing regulations have been made  
19 a part of the commercial fishing regulations. An exception may  
20 be the Columbia River where both the treaty Indian and the all-  
21 citizen fisheries are in the river and are closely related. The  
22 Department of Fisheries wishes to develop direct open and con-  
23 tinued lines of communication with Indian tribes. We hope to  
24 see the day when the Indians will understand and have trust and  
25 confidence in the regulation adoption procedure.

26 Q. What responsibilities will the Department of Fisheries assume in  
27 ensuring that Indians understand fishing regulations and the  
28 basis for their establishment?

29 A. Prior to the setting up of any regulations, the Department will  
30 furnish information to each tribe including the following:

- 31 1. The base upon which the fair share is calculated.
- 32 2. Predicted run sizes.
- 33 3. Expected catch for the year.

- 1 4. Proposed open and closed areas and times.
- 2 5. Proposed fishing gear restrictions.
- 3 6. Calculations of previous seasons catch.
- 4 7. Comparisons with catches from other pertinent fisheries.
- 5 8. Factors affecting run size.
- 6 9. Hatchery plantings which will affect returns and harvest.
- 7 10. Any other pertinent or useful information and data.

8 An example of the type of information furnished to the public  
9 by mail is in Appendix III of the Joint Biological Statement.

10 Q. How will treaty Indians participate in the formulation of regu-  
11 lations for treaty Indians?

12 A. Treaty Indians will be encouraged to become knowledgeable of and  
13 participate in the formulation of regulations for Indian fisheries.  
14 Tribes will be encouraged to contact the department prior to a  
15 hearing so that any counter proposals by the tribe shall not result  
16 from misunderstanding. In addition, there are options in management  
17 for achieving the same goal. The department would seek information  
18 from the tribe as is shown by the following examples:

- 19 1. If fishing is to be limited to 2 days per week, which 2 days  
20 would the tribe prefer? Are weekend days or working days  
21 more desirable to the Indians?
- 22 2. If there are to be daily fishing hours, as are common with gill  
23 net fisheries, what hours are most desirable?
- 24 3. If the catch is to be limited, would the Indians prefer restric-  
25 tions on the length and number of gill nets fished so that  
26 there could be more fishing days, or vice-versa?

27 Q. How would the tribes be informed of any regulations adopted?

28 A. Upon adoption of any regular regulations the department now mails  
29 a copy to the tribal chairman, the tribal secretary, and the tribal  
30 office or council. In the future, it may be desirable to include  
31 the individual fishermen of some tribes. Any fish committees will  
32 be included once their names are made available to the department.  
33 A procedure for contacting fishermen concerning emergency regulations

1 must be worked out with each tribe.

2 Q. Do state laws already provide procedures for involving the Indians  
3 in the regulation-making process?

4 A. Yes. The Administrative Practices Act goes far in safeguarding  
5 the public in that regard, and is followed by the Department of  
6 Fisheries. An outline of the basic elements of this legislation  
7 is to be found in Appendix II of the Joint Biological Statement.  
8 An effort will be made to explain regulation adoption procedures  
9 because Indians must understand such processes before they can be  
10 expected to use them with confidence.

11 Q. Are other avenues of contact open to Indians and to the department?

12 A. Yes. Indians will be consulted or furnished with information from  
13 time-to-time by arrangement of either the tribe or the department.  
14 Most of the information generated by the department is available  
15 upon request. Persons will be made known to the tribes, that they  
16 can feel free to contact for information. Either party should  
17 contact the other if problem areas are foreseen or begin to develop.

18 Q. What agency is best qualified to manage salmon fisheries in the  
19 State of Washington?

20 A. The Department of Fisheries. The elements needed are enabling  
21 legislation, a firm data base and a staff that is experienced and  
22 capable in salmon management. The Department of Fisheries has  
23 these necessary elements and, in addition, is innovative and pro-  
24 gressive in the field of salmon management. The Department of  
25 Fisheries has 50 biologists trained and qualified in data col-  
26 lection and analysis, 40 trained patrol officers whose primary  
27 mission is to protect the resource, 14 trained persons employed  
28 in data processing and statistical analysis, and about 12 adminis-  
29 trative or line supervisory managers. As to education among the  
30 biologists and managers, 43 have bachelors degrees in fisheries or  
31 related sources, eight have masters degrees and two have doctorates.  
32 Their experience averages .75 years as a Biologist I, 8.21 years  
33 at the biologist II level, 12.7 years at the Biologist III level,

1 and 18.7 years at the Biologist IV level. The two research  
2 scientists who have PhD degrees average 14.5 years of experience.

3 Q. Would you outline the background of experience of Washington State  
4 Government in managing fisheries?

5 A. Management began when the Washington territorial legislature dealt  
6 with harvesting procedures in the Columbia River in 1871. Follow-  
7 ing statehood in 1899, management of fisheries began in earnest and  
8 has continued in varying and increasing complexity to this time.  
9 Modern scientific management of salmon truly began following World  
10 War II. Progress has been great by any standards. When I first  
11 started work with the Department of Fisheries in 1951, it was  
12 commonly said that the salmon were on the way out due to fishing  
13 and environmental changes. I heard that in 15 years the salmon  
14 fishery as we knew it would be gone. Twenty-two years have passed,  
15 the salmon fisheries are still here and, more important, no one says  
16 that the salmon fisheries are doomed.

17 Q. What experience does the department have in managing Indian  
18 fisheries?

19 A. Acknowledgement in 1968, due to a U. S. Supreme Court decision,  
20 that recognition and protection of treaty Indian fishing rights  
21 must be a distinct goal of its regulatory program, the Department  
22 of Fisheries began adopting special regulations which allowed  
23 certain treaty Indians to fish by means and at places otherwise  
24 forbidden by State law to Indians and non-Indians. Off-reser-  
25 vation fisheries have been established for the Hoh, Quillayute,  
26 Makah, Tulalip, Puyallup, Nisqually and Squaxin Indians. Even  
27 though their treaty or tribal status is in doubt, Muckleshoot,  
28 Duwamish and Snoqualamie Indians have fished in Lake Washington  
29 and the Duwamish River under permit from the Director of Fisheries.  
30 The regulations adopted are found in Appendix II of the Joint  
31 Biological Statement. More such regulations might have been  
32 adopted, but the guidelines from the Puyallup decision "meet  
33 appropriate standards" and "reasonable and necessary for conservation"

1 are argumentive so that any regulations proposed are opposed by  
2 Indian and other citizens alike with the threat or actuality of  
3 court action. Progress is necessarily slow and difficult under  
4 these conditions.

5 Q. Does the Department of Fisheries possess enough information con-  
6 cerning salmon and fishing to manage an Indian fishery?

7 A. The department has statistics relating to all aspects of managing  
8 the resource including the following:

- 9 1. Catch statistics by area, time, species, gear, etc.
- 10 2. Spawning ground information including area, time, species,  
11 sex ratio, etc.
- 12 3. Catch per unit of effort by gear, time, species, area, etc.
- 13 4. Hatchery releases by river system, numbers, time of release,  
14 size at release, etc.
- 15 5. Biological information on migration, timing by species, river  
16 system, etc.
- 17 6. Historical records.

18 Q. Does any other organization possess such a data base?

19 A. No, it is and has been the responsibility of the Department of  
20 Fisheries to collect and analyze all such data. Other organizations  
21 such as Federal agencies or the University of Washington have some  
22 of the data mentioned; however, they use the data base of the  
23 Department of Fisheries in any in depth or comprehensive studies  
24 or analysis.

25 Q. Does the Department make use of machines for storing, processing  
26 and analyzing data?

27 A. Yes, along with other standard equipment, the department is using  
28 the latest (third generation) computer equipment, an IBM Model 65.  
29 This equipment generates statistical reports in one-to-ten minutes  
30 which would take approximately 30 people 3 calendar months to produce.  
31 Great amounts of information are therefore available for use on a  
32 day-to-day basis as needed. Experiments are designed and computer  
33 models constructed and used so that the management capabilities

1 of the Department of Fisheries is increasing at a steady rate.  
2 For example, F-21, which I will use for illustrative purposes,  
3 demonstrates the value and use of computer capability. It portrays  
4 the catch of coho salmon as the run progressed through the Puget  
5 Sound fishery. It shows the size of the catch each day by manage-  
6 ment area with each star representing 100 salmon and the blank  
7 spaces indicate days closed to fishing. In the Strait of Juan de  
8 Fuca, it will be noted on page 1 of the exhibit, a sizeable catch  
9 was made in July and August. These were the Fraser River run of  
10 salmon which are quite early compared to the Puget Sound runs.  
11 They never do enter Puget Sound proper. Curtailment of the fishery  
12 on that group of salmon would have had little or no effect on  
13 Indian fisheries in the case area. The run represented by catches  
14 in early August represented salmon bound for Puget Sound, and the  
15 progression of that run can be followed on page 2 of the exhibit,  
16 into Admiralty Inlet along Whidbey Island. From that point it can  
17 be seen that coho salmon rapidly spread throughout Puget Sound.  
18 You will note that the catch on September 13th is high. This date  
19 was the opening of the season. The high catch represents an  
20 accumulation of salmon and does not reflect the migration pattern  
21 of the run. The figure portraying the central Puget Sound catch  
22 on page 3 reflects emergency changes made as the run and catch  
23 progressed. You will note the extremely good catches on the  
24 opening day, September 13th, were followed by an extreme decline  
25 on the 14th, 15th and 16th. This led the department to believe  
26 that the run might be small but early in timing, and protection was  
27 needed. The following week two days of fishing were allowed and  
28 catches did indicate a small run. Two days only of fishing were  
29 scheduled for the next fishing week, but catches on September 27th  
30 and September 28th indicated new run strength and two more fishing  
31 days were allowed that week. From then on catches declined because  
32 the run was ending and the salmon not caught had passed into salmon  
33 preserves and rivers closed to the commercial fleet. Much other

1 data is processed and used simultaneously with these print-outs,  
2 such as: fishing fleet size, the catch per unit of effort, the  
3 distribution of the fishing fleet, the geography of the areas  
4 fished, the speed of salmon migration, the relative numbers of  
5 hatchery and wild fish, the efficiency of the fishing gear, and the  
6 presence of other species of salmon at the same time.

7 Q. How is the department equipped to carry out the research and  
8 development necessary to manage on a fair-share percentage basis?

9 A. A capable staff is a key element in research and development, and  
10 I have commented on the qualifications of our staff. Good equip-  
11 ment must be at hand and the department is sufficiently equipped  
12 for the needed experimental work or can arrange for necessary  
13 equipment. The department has much waterborne gear, mobile  
14 trailers with scientific equipment, field laboratories, etc.  
15 Further, hatchery science is improving rapidly and is maintaining  
16 flexibility and adaptability so that hatchery capabilities will be  
17 a major aid in any salmon management plan developed.

18 Q. Does any other agency have an ability to manage salmon fisheries  
19 in Washington comparable to that of the Washington Department of  
20 Fisheries?

21 A. No other agency has the data base, staff, management experience  
22 or knows the state of the art in managing fisheries in Washington  
23 as does the Washington Department of Fisheries. This is due to  
24 the responsibility, organization, and experience of the department  
25 as well as to a progressive attitude toward fisheries management.

26 Q. Are Indian tribes capable of proper salmon management?

27 A. No, they are not for several reasons.

- 28 1. They lack authority and have not shown the will or ability to  
29 exercise control of tribal fishermen in off-reservation areas.
- 30 2. They do not possess an adequate data base in their own fishing  
31 area, let alone the information necessary to balance their fishery  
32 with the all-citizen fishery.
- 33 3. Indian tribes do not have a staff of expert fishery managers.

1 They do have good fishermen but that is quite another thing.

2 Q. Do you know of examples of poor management by Indian tribes?

3 A. Yes, one example is the catch of sockeye from the Ozette River.

4 The Ozette River flows from Ozette Lake to the Pacific Ocean in  
5 the extreme northwest corner of the State. The area is unpolluted  
6 and, since few sockeye salmon are taken by the Washington ocean  
7 troll fleet and net fishing for salmon in the ocean is not allowed,  
8 virtually the entire run enters the river. Little fishing had  
9 gone on for some time due to the remoteness of the area which had  
10 led to abandonment of Indian residence in the area. Indians once  
11 again began net fishing for sockeye salmon in the Ozette River and  
12 in 1948 the catch was about 4,000 salmon. Catches rose to over  
13 17,000 salmon and by 1952, one cycle of salmon later, had fallen  
14 to about 3,000 salmon. As is illustrated in Exhibit F-22, catches  
15 have continued to decline and now number less than 500 salmon  
16 annually. The Ozette River salmon run was grossly overfished by  
17 Indians on the Ozette reservation, and continued fishing of the  
18 remnant run left is preventing its recovery.

19 The Quinault River sockeye run is managed by the Quinault  
20 Indian tribe. The spawning tributaries above Lake Quinault and  
21 the lake are in relatively their native state. It is true that the  
22 river and its tributaries shift about considerably which does affect  
23 spawning, but the river has always done so by its nature. Even  
24 though regulated by the tribe, sockeye salmon catches on the average  
25 have steadily declined over the years. Exhibit F-23 illustrates  
26 Quinault sockeye catches since 1936. Prior to 1950, catches  
27 exceeded 200,000 on two years. Prior to 1957, catches exceeded  
28 100,000 salmon on eight years. Since 1956 the catch has never  
29 reached 100,000 salmon. Exhibit F-4 shows the catch of chinook  
30 salmon by Puyallup Indians and the return of adults to the Puyallup  
31 hatchery. The very large catch in the early 1960's precipitated  
32 the Puyallup court case and was followed by a period of no fishing  
33 so that the run might be re-built. Then the Puyallup Indians and

1 the Federal Government claimed that Indians could fish as they  
2 chose within the boundaries of the old reservation and catches of  
3 chinook rose markedly in 1971 and 1972. About 1,000 chinook salmon  
4 are required by the Puyallup Washington State salmon hatchery.  
5 Keeping in mind that the catch or hatchery take in one year affects  
6 the return of salmon 3 and 4 years later, it can be seen that the  
7 large catches in the 60's is related to a poor hatchery return with  
8 no Indian fishing following 1965. The run was recovering following  
9 the closure of the river to fishing in 1966, as can be seen by the  
10 steady increase in the hatchery escapement in 1967, 1968, 1969 and  
11 1970. The increase in the Indian catch in 1971 and 1972 has once  
12 again dropped the hatchery run below a level needed for hatchery  
13 operation. Since hatchery chinook salmon have a higher survival  
14 rate than do wild fish, over-fishing has a much greater impact on  
15 wild fish. The wild stocks of salmon have suffered severely from  
16 over-fishing by Puyallup Indians. As is shown in Appendix III,  
17 Table 5 of the Joint Biological Statement, in 1971 the department  
18 of Fisheries set one day each week of fishing from August 15 through  
19 September 18 to protect the expected poor chinook run. In that  
20 year Puyallup Indians sold chinook salmon on 31 days prior to  
21 September 18. Both the hatchery and wild segments of the run were  
22 over-fished. Once a chinook run is fished to a low level it takes  
23 a minimum of three cycles, or 12 years, to expect recovery. The  
24 Puyallup Indians effectively undid the recovery of the chinook  
25 stocks of the Puyallup River from the previous over-fishing. In  
26 spite of the many effects of civilization on the Puyallup River  
27 system, it is a good salmon stream. It is my opinion that, properly  
28 managed, a treaty Indian catch of between four and 5,000 chinook  
29 salmon could be maintained. Added hatchery production might  
30 increase that level.

31 Q. Does the Department of Fisheries plant hatchery-reared salmon which  
32 contribute significantly to Indian catches of salmon?

33 A. Yes. Table 29 of the Joint Biological Statement shows salmon plants

1 into the watershed of the Skokomish River, Nisqually River,  
2 Nooksack River, Puyallup River, Skagit River, Snohomish River,  
3 Sooes River and Quillayute River, all of which border or flow  
4 through Indian reservations. Of the 14 Department of Fisheries  
5 hatcheries shown in Figure 43 of the Joint Biological Statement,  
6 eight are located on streams which presently support an Indian  
7 fishery. These plantings augment the Indian catch and often to a  
8 high degree, as is shown by the following example. Exhibit F-19  
9 shows that the catch of chinook salmon by Skokomish Indians from  
10 the Skokomish River did not reach 1,000 salmon prior to the con-  
11 struction and operation of George Adams Hatchery. On the first  
12 return of four-year-old chinook salmon, the catch was nearly 3,000  
13 salmon and now ranges between 5,000 and 13,000 salmon annually.  
14 Catches of chinook salmon by Skokomish Indians are roughly 10 times  
15 those prior to the operation of the hatchery.

16 Q. Will successful management of treaty Indian fisheries depend in  
17 any way upon cooperation with Indian tribes?

18 A. Once a fair share is established so that Indians and non-Indians  
19 alike will have an objective measure of the Indian right, cooperation  
20 between the State and the Indian tribes will be much easier.  
21 Cooperation will be beneficial to Indian fishermen and useful in  
22 fisheries management. A fishery is for people and if they understand  
23 and can take part in management, regulations are easier to enact  
24 and enforcement is a routine matter. Much time, energy and money  
25 is saved and human happiness is increased. Cooperation will ensure  
26 that fisheries regulations are adapted to the Indian way of life  
27 and the business atmosphere of the tribes. A number of fishing  
28 regulations which do not matter one way or the other to the state  
29 could be adopted at the wishes of the tribe.

30 Q. Does the Department of Fisheries work in cooperation with Indian  
31 tribes aside from regulatory matters?

32 A. The department has a long history of working with Indian people  
33 which has persisted even at times when tensions were high regarding

1 treaty rights. The Department and Indians have a broad common  
2 interest in salmon which has enabled us to stay in communication  
3 with, know as individuals, and work with most Indian tribes. The  
4 following examples are not exhaustive but provide an overview of  
5 programs whereby the department works with Indian tribes.

6 1. Salmon eggs provided for educational purposes

7 Example - The Skokomish Indian people, through guidance pro-  
8 vided by a fisheries biologist from Small Tribes Organization  
9 of Western Washington, Inc., have developed a small educational  
10 salmon egg-hatching station on their reservation. The Washington  
11 Department of Fisheries has provided the chum eggs necessary  
12 for this small educational hatchery since its beginning,  
13 approximately 3 years ago. In 1972, the department provided  
14 100,000 eggs for this station.

15 2. Hatchery releases of juvenile salmon made at such locations as  
16 to provide maximum harvest by Indian fisheries

17 Example - Two Department of Fisheries-operated salmon hatcheries  
18 are located within Hood Canal's drainage system. The George  
19 Adams Salmon Hatchery is located on a tributary of the Skokomish  
20 River immediately above the Skokomish Indian Reservation, while  
21 the Hoodspport Salmon Hatchery is located at Hoodspport on a  
22 small tributary of Hood Canal. Both hatcheries produce coho  
23 and chinook salmon. The Hoodspport Hatchery has also been able  
24 to develop relatively small pink and chum runs.

25 In order to reduce the numbers of adult salmon which have  
26 returned to these two stations in excess of the department's  
27 propagation requirements, the department has developed a  
28 program highly beneficial to the Skokomish Reservation Indian  
29 fishermen.

30 Coho eggs for both stations are taken at the George Adams  
31 Hatchery while fall chinook eggs, for both stations, are taken  
32 at the Hoodspport Hatchery. River flows at time of coho entry  
33 into the Skokomish River are such that coho escapement to the

1 hatchery is ensured. Thus, maximum harvest effort on both  
2 chinook and coho is beneficial to the Indian fishery without  
3 damaging the resource.

4 This management procedure resulted in approximately 21,800  
5 coho being caught by Skokomish Indian Reservation fishermen  
6 in 1970. Of those coho caught of hatchery origin, 50% were  
7 estimated to have been produced by the Hoodspport Hatchery. An  
8 additional 12,700 fall chinook were caught while only 1,356  
9 fall chinook were allowed to escape to the George Adams Hatchery.  
10 With George Adams' fall chinook eggs ensured from Hoodspport  
11 Hatchery, this relatively small escapement has not been cause  
12 for concern in the past.

13 3. Hatchery production released into non-hatchery streams

14 Example - One of the few rivers on which an Indian reservation  
15 is located in Puget Sound, which does not have a salmon hatchery  
16 on it, is the Nisqually River. However, to supplement the  
17 natural production of this river, the Department of Fisheries  
18 has made hatchery releases into this stream from its hatcheries  
19 located elsewhere. In 1971, 5,865 lbs. of fall chinook fry  
20 and 27,419 lbs. of coho yearlings of state hatchery-reared fish  
21 were released into the Nisqually River. This program was  
22 continued in 1972 and is programmed for 1973.

23 These plants will increase the number of salmon returning  
24 to the Nisqually River above those which are produced naturally,  
25 thereby increasing the number of salmon available to be caught  
26 by the Nisqually Indian fishermen.

27 4. Hatchery production releases into barren areas

28 Example - The headwaters of the Klickitat River originate on  
29 or above the Yakima Indian Reservation. Construction of fish  
30 passage facilities in the upper river at Castile Falls has  
31 opened an additional 20 miles of spawning and rearing area.  
32 Spring chinook and coho salmon juveniles have been and are  
33 being released into the upper river to take advantage of this

1 potential production area and in an attempt to establish a  
2 natural run above the fishways.

3 Any additional production realized from this program directly  
4 benefits the Yakima Indian dip net fishery located on the  
5 Klickitat River near its mouth as well as all Columbia River  
6 fishermen, Indian and non-Indian, both commercial and sport.

7 5. Salmon runs developed where none existed previously

8 Example - Several low-water upstream migration blocks occurred  
9 naturally in the Klickitat River (RM 2.2) prior to 1955 when  
10 the last fishway at these lower falls was completed. Due to  
11 these falls, only spring chinook were able to migrate into the  
12 Klickitat River prior to this time. Spring chinook, migrating  
13 upstream during high-flow periods, were able to negotiate the  
14 falls. In 1945 and 1951, respectively, fall chinook and coho  
15 were introduced into the Klickitat River in anticipation of  
16 the fishways being completed and used by these species.

17 In 1950, construction on the Klickitat River Salmon Hatchery  
18 was begun. Construction was completed in 1954. A total of  
19 4,551,542 salmon juveniles consisting of spring chinook year-  
20 lings, fall chinook yearlings, and coho yearlings were released  
21 by this station in 1972. The 1971 Klickitat River Indian dip  
22 net fishery reported catch was 289 spring chinook, 2,466 fall  
23 chinook, and 4,055 coho.

24 6. Cooperate State-Indian fresh-water rearing programs

25 Example - The Tulalip Indian Reservation contains an ideal  
26 fresh-water rearing pond of approximately 2-1/2 surface acres  
27 with a direct outlet into Tulalip Bay. An agreement between  
28 the Department of Fisheries and the Indians was reached in the  
29 fall of 1970 for this pond to be used to rear coho salmon  
30 juveniles with the state supplying the fish and feed while the  
31 tribe supplied the necessary manpower and need. The fish were  
32 provided to the tribe in February, approximately 3 months prior  
33 to their normal release period. Natural spawning area is not

1 available at this rearing location, and the eggs are not  
2 needed by the Skykomish Hatchery. Thus, total harvesting  
3 effort is allowed on the reservation (Tulalip Bay) after the  
4 adult fish have passed through an extensive commercial net and  
5 sport fishery conducted by both Indian and non-Indian fishermen.

6 In 1971, 28,333 lbs. of coho yearlings, 50% of the Skykomish  
7 Hatchery coho production, were released from this pond. In  
8 1973, an evaluation of the comparative production success of  
9 this program was begun by marking approximately 50,000 coho  
10 juveniles at the Skykomish Hatchery. These fish are to be  
11 released (along with 450,000 other coho juveniles) into this  
12 pond to again be fed and released as yearling coho in the  
13 spring of 1973. Indian people were hired to mark these fish  
14 with funds supplied through the Bureau of Sport Fisheries and  
15 Wildlife and with equipment and facilities supplied by the  
16 Department of Fisheries. In 1973, 25% of the feed costs for  
17 this program will be supplied by the Tulalip Indian Tribe.

18 7. Cooperative State-Indian salt-water rearing program

19 Example - The department has cooperated fully with the Squaxin  
20 Island Indian mariculture program since its inception several  
21 years ago. The department has provided the chinook which the  
22 Squaxins rear in their salt-water ponds. In exchange, the  
23 Squaxins have released a specific poundage of relatively large  
24 salt-water reared chinook which have contributed to the local  
25 sport fishery at a very high rate. These delayed release and  
26 large chinook (2 to 3 per pound as compared to 100 per pound  
27 normal hatchery release size) tend to remain in Puget Sound and  
28 enter sport fishery catches.

29 In 1972, 6,000 lbs. of fall chinook were provided to the  
30 Squaxins. A total of 17,500 lbs. of chinook is presently being  
31 released by the Squaxins for the department. These fish have  
32 been marked and the catches will be evaluated in the continuing  
33 program of enhancing Puget Sound sport fisheries.

1 8. State-Federal cooperative salmon plantings into reservation  
2 waters

3 The Bureau of Sport Fisheries and Wildlife operates the  
4 Quilcene Salmon Hatchery on the Olympic Peninsula. The  
5 hatchery facility programs several plantings into rivers  
6 running through Indian reservations. One example is the White  
7 River (Muckleshoot Reservation), a major tributary of the  
8 Puyallup River.

9 However, due to disease organisms which are specific to  
10 the area of the Quilcene Hatchery, the Department of Fisheries  
11 does not want these fish released into inner Puget Sound rivers.  
12 Therefore, rather than simply bar this transfer of fish, the  
13 Department of Fisheries releases salmon juveniles into the  
14 White River from its Puyallup Hatchery. In turn, the Quilcene  
15 Hatchery releases an equal poundage of young salmon into the  
16 streams of our choice of the Olympic Peninsula.

17 9. Hatchery surplus salmon carcass give-away programs

18 The department's hatchery system usually receives salmon in  
19 excess of its propagation needs, especially coho salmon. It  
20 is the department's policy to provide numbers of these fish,  
21 which are fit for human consumption, to our economically-  
22 depressed Indian people.

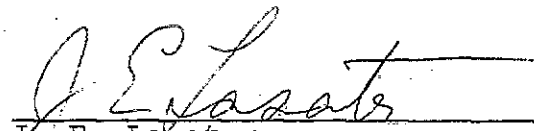

23 Indian tribal representatives are contacted when these fish  
24 are available and it is their responsibility to see that these  
25 fish are distributed to their respective tribal members. In  
26 1972, 256,194 lbs. of salmon which had returned to the  
27 department's hatcheries were provided to Indian people.

28 10. Cooperative State-Indian rearing programs which provide maximum  
29 benefit to all resource user groups

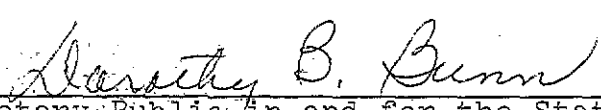

30 Example - The Lummi Indians are operating a salmon and steelhead  
31 hatchery on Skookum Creek, a tributary of the Nooksack River.  
32 Once this hatchery is able to develop its own salmon runs, its  
33 future egg source will be ensured. Until this time, however,

1 the Department of Fisheries has agreed to supply this Indian  
2 hatchery with eyed-eggs at approximate cost or by having the  
3 Indians release a pre-agreed upon number of juveniles in lieu  
4 of any monetary exchange. In this manner, the salmon resource  
5 of this area will have been increased to the benefit of all  
6 citizens while placing a minimum financial burden on all  
7 interested parties.

8 Included also are two letters, marked Exhibits F-24 and F-25  
9 for illustrative purposes, one from the department to an Indian  
10 tribe and one from an Indian tribe to the Department, which  
11 show the advantage of mutual benefit through cooperation.
